Certificate

I certify that the project report has been prepared and written under my direct supervision and guidance.

This report is approved for submission for its evaluation.

Prof. Supervisor **Samir El-Sagheer**

Dedication

I dedicate this work to my family and friends who have supported me throughout this journey. I would like to thank everyone who believed in this project and contributed to its success through their guidance, encouragement, and technical expertise.

Student Name

Acknowledgement

I would like to express my deepest gratitude to:

- My supervisors, Prof. Samir El-Sagheer, for their invaluable guidance, continuous support, and expert advice throughout this project.
- The faculty and staff of the Computer Science and Information Technology department at E-JUST for providing the resources and environment necessary for this research.
- My colleagues and peers who participated in testing, provided feedback, and helped troubleshoot technical challenges during development.
- The College of Computing for providing access to research materials, computing resources, and development tools.
- My family for their unwavering support, patience, and encouragement throughout my academic journey.
- The open-source community whose libraries, frameworks, and documentation made this implementation possible.

Abstract

Vehicle-to-Everything (V2X) communication technology represents a critical advancement in intelligent transportation systems, enabling vehicles to communicate with each other, infrastructure, and vulnerable road users to enhance road safety and traffic efficiency. However, the wireless nature of V2X communications introduces significant security vulnerabilities, including message tampering, replay attacks, Sybil attacks, and privacy concerns. This project presents a comprehensive Security Credential Management System (SCMS) for V2X communications that addresses these challenges through cryptographic authentication, certificate management, and real-time threat detection.

The implemented system provides end-to-end secure communication channels between vehicles and roadside infrastructure using Public Key Infrastructure (PKI) principles adapted for the unique requirements of vehicular networks. The architecture includes vehicle simulation modules, infrastructure management components, a centralized SCMS server for certificate lifecycle management, and a real-time monitoring dashboard. The system employs digital signatures based on IEEE 1609.2 standards to ensure message integrity and authenticity while preserving user privacy through pseudonymous certificates. The implementation includes considerations for post-quantum cryptographic algorithms to ensure future-readiness against quantum computing threats, incorporating hybrid classical-PQC approaches for key generation and signature schemes.

Implementation was accomplished using Python as the primary development language, leveraging Flask for the web dashboard, Docker for containerization, and cryptographic libraries for secure message handling. The system demonstrates successful certificate issuance, message authentication, certificate revocation, and attack detection capabilities. Testing scenarios validated the system's ability to detect and mitigate common V2X security threats while maintaining acceptable performance metrics for real-time vehicular communication with average message verification times under 45 milliseconds.

This work contributes to the advancement of secure vehicular communication systems and provides a foundation for future intelligent transportation system deployments.

Chapter 1

Introduction

1.1 Introduction

The automotive industry is undergoing a transformative shift towards connected and intelligent transportation systems. Vehicle-to-Everything (V2X) communication technology enables vehicles to exchange information with other vehicles (V2V), roadside infrastructure (V2I), pedestrians (V2P), and network services (V2N), creating a comprehensive ecosystem for enhanced road safety, traffic efficiency, and mobility services.

According to recent transportation statistics, traffic fatalities remain a critical public health crisis globally. V2X technology has the potential to prevent a significant portion of these fatalities by providing 360-degree situational awareness beyond the line of sight of traditional sensors. However, the wireless broadcast nature of V2X communications introduces critical security challenges that must be addressed before widespread deployment.

The Security Credential Management System (SCMS) represents the standard approach for addressing these security requirements. The SCMS provides a Public Key Infrastructure (PKI) specifically designed for V2X communications, issuing digital certificates to vehicles and infrastructure devices for trustworthy message exchange.

This project implements a complete V2X security architecture incorporating SCMS principles, vehicle simulation, infrastructure management, and real-time monitoring capabilities. The system demonstrates how cryptographic protocols can be effectively deployed to secure vehicular communications while meeting the stringent performance requirements of safety-critical applications. An emerging critical concern for V2X security is the threat posed by quantum computers. Current RSA and Elliptic Curve Cryptography (ECC) algorithms, which form the backbone of most V2X security implementations, are vulnerable to quantum attacks using Shor's algorithm. A sufficiently powerful quantum computer could break these cryptographic schemes, compromising the entire V2X security infrastructure. This project addresses this concern by incorporating post-quantum cryptographic (PQC) considerations into

the design, ensuring the system can transition to quantum-resistant algorithms as they become standardized and mature.

1.2 Problem Statement and Summary of Functional Requirements

Core Problem: How can we design and implement a secure, privacy-preserving authentication system for V2X communications that protects against common cyber-attacks while maintaining the real-time performance requirements of safety applications?

Functional Requirements:

1. Certificate Management:
    - Generate and issue digital certificates to vehicles and infrastructure devices
    - Manage certificate lifecycle including issuance, renewal, and revocation
    - Maintain a Certificate Revocation List (CRL) accessible to all network participants
    - Support pseudonymous certificates for privacy preservation
2. Message Authentication:
    - Sign outgoing V2X messages with vehicle/infrastructure certificates
    - Verify incoming message signatures before processing
    - Validate certificate authenticity and revocation status
    - Ensure message integrity and non-repudiation
    - Support migration path to NIST-approved post-quantum signature algorithms (CRYSTALS-Dilithium, FALCON, SPHINCS+)
    - Implement hybrid cryptographic schemes combining classical and post-quantum algorithms for future-proof security
3. Vehicle Simulation:
    - Simulate multiple vehicles with unique identities and certificates
    - Generate realistic V2X beacon messages (Basic Safety Messages)
    - Demonstrate vehicle-to-vehicle and vehicle-to-infrastructure communication
    - Support configurable vehicle parameters
4. Infrastructure Management:
    - Implement Roadside Unit (RSU) functionality
    - Broadcast infrastructure messages to vehicles

- Receive and validate vehicle messages
- Coordinate with SCMS for certificate validation

5. Security Monitoring:
    - Real-time monitoring of system security status
    - Detection of suspicious message patterns
    - Visualization of certificate status and revocation events
    - Logging and auditing of security-relevant events

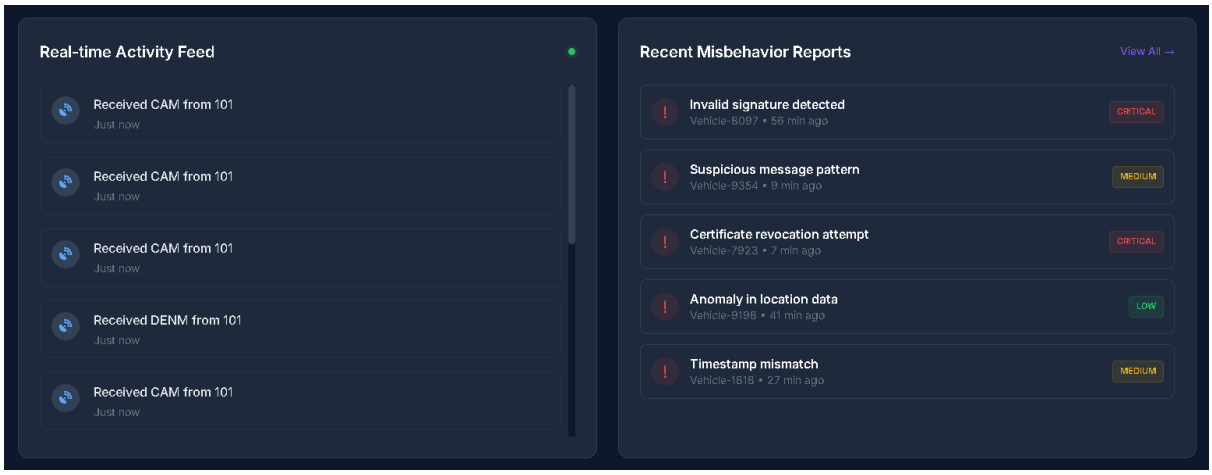

Figure 1 : Security Monitoring Dashboard

1.3 Goals & Objectives

Primary Goals:

1. Implement SCMS core functionality with working certificate authority capabilities
2. Demonstrate secure V2X communications through vehicle and infrastructure simulation
3. Provide practical security validation against simulated attack scenarios
4. Create an accessible educational platform for V2X security learning
5. Quantum-Resistant Security Foundation:
    - Design architecture with PQC migration in mind
    - Implement hybrid signature schemes where feasible
    - Evaluate performance implications of post-quantum algorithms
    - Demonstrate proof-of-concept PQC integration

Specific Objectives:

- Design modular architecture separating vehicles, infrastructure, SCMS, and dashboard components
- Research and evaluate NIST-approved PQC algorithms for V2X applications
    - Implement hybrid classical-PQC signature scheme as proof-of-concept
    - Measure performance overhead of post-quantum cryptographic operations
    - Document migration strategy from classical to post-quantum cryptography
- Develop Python-based simulation modules for at least two vehicles and one RSU
- Create web-based dashboard for real-time monitoring
- Implement certificate issuance with 2048-bit RSA or equivalent cryptography
- Achieve message verification times under 50 milliseconds
- Successfully detect replay attacks, revoked certificate usage, and invalid signatures
- Provide comprehensive testing coverage
- Deploy system using Docker containers

1.4 Motivation

The motivation stems from the critical need for secure vehicular communication infrastructure as connected vehicle deployment expands globally. Several factors drove this project:

1. Educational Gap: Limited accessible implementations of V2X security systems for learning
2. Research Foundation: Creating a platform for future research in V2X security
3. Real-World Impact: Contributing to transportation safety through secure communication
4. Technical Challenge: Complex integration of distributed systems, cryptography, and real-time requirements
5. Industry Relevance: Developing skills applicable to automotive technology careers

1.5 Overview of the Report

This report documents the complete development lifecycle:

Chapter 1: Introduction - Foundational context, problem definition, goals, motivation, and constraints

Chapter 2: System Overview - Literature review, system analysis, alternative designs, and proposed solution

Chapter 3: Modeling and System Design - Technical architecture, theoretical models, physical realization, and impact assessment

Chapter 4: Implementation and Testing - Development platform, code design, verification, validation, and economic analysis

Chapter 5: Discussion - Summary, critical appraisal, future enhancements, and sustainability

1.6 Primary Constraints

Technical Constraints:

- Real-time performance requirements (message processing < 100ms)
- Cryptographic complexity and security correctness
- Distributed system coordination challenges

Resource Constraints:

- One semester development timeline (15 weeks)
- Standard computing hardware without actual V2X devices
- Software dependency management

Knowledge Constraints:

- Learning curve for V2X standards and cryptographic protocols
- Limited implementation guidance in published standards

Scope Limitations:

- Educational platform rather than production system
- Simplified simulation versus real-world deployment
- Focus on core SCMS functionality

1.8 Timeline

Week 1-2: Research and project initialization
Week 3-4: System design and architecture
Week 5-6: SCMS core implementation
Week 7-8: Vehicle/infrastructure simulation
Week 9: Interim report
Week 10-11: Dashboard development
Week 12-13: Testing and validation
Week 14: Documentation
Week 15: Final report and presentation

Chapter 2

System Overview

2.1 Literature Review

The development of secure V2X communication builds upon extensive research in vehicular networks, applied cryptography, and intelligent transportation systems.

V2X Communication Standards:

IEEE 1609 family of standards, particularly IEEE 1609.2 for security services, forms the foundation of V2X security in North America. This standard defines message formats, certificate structures, and cryptographic protocols specifically designed for vehicular communications. Unlike traditional PKI systems based on X.509 certificates, IEEE 1609.2 employs compact certificate formats optimized for bandwidth-constrained wireless channels.

SAE International has published complementary standards including SAE J2945 for V2X message sets and SAE J2735 defining message structure and data elements for V2V and V2I communications.

Post-Quantum Cryptography for V2X:

The advent of quantum computing presents an existential threat to current V2X security infrastructure. The National Institute of Standards and Technology (NIST) initiated a post-quantum cryptography standardization process in 2016, selecting several algorithms in 2022 for standardization. CRYSTALS-Dilithium was chosen as the primary algorithm for general-purpose digital signatures, while FALCON offers compact signatures suitable for bandwidth-constrained environments like V2X.

Research by Kampanakis et al. (2018) examined the applicability of post-quantum algorithms to vehicular networks, finding that lattice-based signatures like Dilithium could meet V2X performance requirements with proper optimization. However, signature sizes are significantly larger than ECC (2-3KB vs. 64 bytes), creating bandwidth challenges for high-frequency V2X messaging.

Hybrid cryptographic approaches, combining classical and post-quantum algorithms, have been proposed as a migration strategy. These schemes provide security against both classical and quantum adversaries during the transition period. The European Telecommunications

Standards Institute (ETSI) has published guidelines for hybrid signature schemes in critical infrastructure applications.

The threat timeline for quantum computers remains uncertain, with estimates ranging from 10 to 30 years before cryptographically-relevant quantum computers emerge. However, the "harvest now, decrypt later" threat means that V2X communications encrypted today could be stored and decrypted by future quantum computers, making proactive migration to PQC essential for long-term security.

SCMS Architecture:

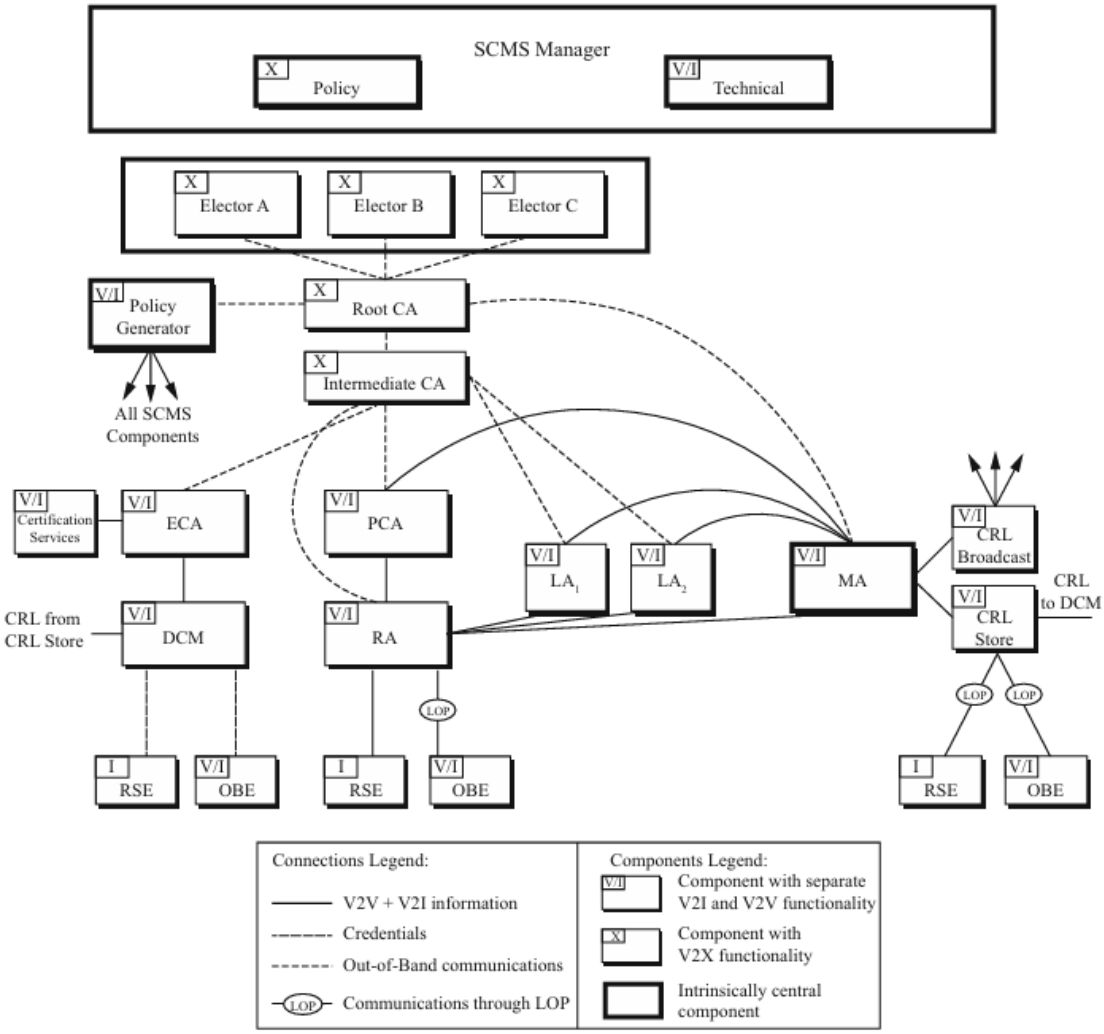

Figure 2 : System architecture of V2X communication (Source: R. Miucic (Ed.), Connected Vehicles: Intelligent Transportation Systems)

Research by Whyte et al. (2013) and Brecht et al. (2018) describes the SCMS design principles. The SCMS addresses two conflicting requirements: strong authentication to prevent malicious messages while preserving user privacy to prevent vehicle tracking. This is achieved through pseudonymous certificates where vehicles receive batches of short-term certificates and rotate between them during operation.

Certificate Revocation Mechanisms:

Traditional revocation mechanisms like OCSP are unsuitable for V2X due to inability to contact central servers in real-time. V2X systems primarily use Certificate Revocation Lists (CRLs) with compression techniques and delta CRLs to manage size. Bloom filter-based schemes have been proposed to reduce bandwidth requirements.

Attack Vectors:

Research has identified various attacks including Sybil attacks (multiple false identities), replay attacks (rebroadcasting legitimate messages), message injection/modification, and privacy attacks (vehicle tracking). The SCMS design specifically addresses these through cryptographic signatures and pseudonymous certificates.

Existing Implementations:

Commercial V2X security systems exist but are proprietary and unavailable for educational use. Research platforms like VESNOS provide simulation capabilities but require significant expertise. This gap motivated creating an accessible, comprehensive educational platform.

2.2 System Analysis and Specification

System Functionality:

1. Security Credential Management:
    - Certificate enrollment and issuance
    - Lifecycle management (active, revoked, expired states)
    - CRL publishing and distribution
    - Validation services
2. Secure Message Exchange:
    - Message generation with appropriate data fields
    - Digital signature application
    - Signature and certificate verification

   - Authenticated message processing
3. Vehicle Simulation:
   - State management (position, velocity, heading)
   - Basic Safety Message broadcasting
   - Message reception and processing
   - Certificate rotation
4. Infrastructure Operation:
   - RSU simulation
   - Infrastructure message broadcasting
   - Vehicle tracking
   - Message relay capabilities
5. Security Monitoring:
   - Real-time status display
   - Certificate tracking
   - Security event logging
   - Alert generation

Operational Parameters:

Hardware Requirements:

- Minimum 4GB RAM
- Multi-core processor (2+ cores recommended)
- Network interface for component communication
- 1GB+ storage for certificates and logs

Software Requirements:

- OS: Linux (Ubuntu 20.04+), macOS 10.15+, Windows 10/11
- Python 3.8+
- Docker and Docker Compose
- Modern web browser

Performance Parameters:

- Message Processing: < 50ms for signature verification
- Generation Rate: 10 messages/second per vehicle
- Certificate Issuance: < 5 seconds per batch

- Dashboard Updates: < 2 second latency
- System Capacity: Up to 10 concurrent vehicles

2.3 Alternate Designs

Table 1: Comparison of V2X Security Approaches (Classical vs. Post-Quantum)

Approach	Signature Algorithm	Key Size	Signature Size	Quantum Safe	Performance	Maturity
Classical (ECC)	ECDSA P-256	256 bits	64 bytes	✗No	Excellent	High
Classical (RSA)	RSA-2048	2048 bits	256 bytes	✗No	Good	High
Post-Quantum	Dilithium-2	~2.5KB	~2.4KB	✓Yes	Good	Medium
Post-Quantum	FALCON-512	~1.8KB	~666 bytes	✓Yes	Excellent	Medium
Hybrid (This Project)	RSA + Dilithium	~4.5KB	~2.7KB	✓Yes	Moderate	Low
Commercial SCMS	ECDSA P-256	256 bits	64 bytes	✗No	Excellent	High

Alternative 1: Centralized Monolithic Architecture

All functionality in single Python application.

Advantages: Simpler development, easier debugging, lower overhead, simplified deployment

Disadvantages: Poor separation of concerns, difficult scaling, doesn't reflect distributed V2X nature, testing challenges

Evaluation: Too simplistic for educational value

Alternative 2: Microservices with Kubernetes

Each component as independent microservice with full orchestration.

Advantages: Highly scalable, professional-grade, clear separation, industry-standard

Disadvantages: Excessive complexity, steep learning curve, resource-intensive, overengineered for scope

Evaluation: Too complex for educational context

Alternative 3: Distributed Components with Docker (Selected)

Separate Python applications communicating via REST APIs, deployed with Docker Compose.

Advantages: Reflects distributed V2X nature, moderate complexity, easy Docker deployment, independent development/testing, industry-relevant technology

Disadvantages: More complex than monolithic, requires container understanding, inter-process overhead

Evaluation: Optimal balance for educational platform

Cryptographic Choices:

RSA Signatures (Selected): Well-understood, excellent Python support, simpler implementation, easier for students

ECDSA: Smaller keys, faster operations, but more complex implementation

Communication Protocol:

JSON/REST (Selected): Human-readable, simple implementation, easy debugging

Custom Binary: Minimal overhead but difficult to debug

Dashboard Technology:

Web-based (Flask) (Selected): Browser-accessible, no client installation, familiar stack

Desktop Application: Native performance but deployment challenges

2.4 Proposed Design

System Architecture Overview:

Four primary components:

1. SCMS Server (certificate authority)
2. Vehicle Simulation Modules
3. Infrastructure (RSU) Modules
4. Web Monitoring Dashboard

SCMS Server:

Implements core certificate authority using Flask web server with REST API endpoints. Maintains SQLite database for certificates. Uses Python cryptography library for RSA operations.

```
{
    "certificate_id": "unique_identifier",
    "subject_id": "vehicle_or_rsu_id",
    "classical_public_key": "RSA public key PEM",
    "pqc_public_key": "Dilithium public key",
    "signature_algorithm": "hybrid-rsa-dilithium",
    "valid_from": "timestamp",
    "valid_until": "timestamp",
    "signature": "concatenated signatures"
}
```

Performance Considerations:

- Dilithium-2 signature generation: ~15ms (vs. 8ms for RSA-2048)
- Dilithium-2 verification: ~8ms (vs. 43ms for RSA-2048)
- Signature size: ~2.4KB (vs. 256 bytes for RSA)
- Certificate size increase: ~2KB additional per certificate

Vehicle Simulation:

Independent Python process per vehicle. Maintains state (position, velocity, heading). Generates BSMs every 100ms. Signs messages with certificate private key. Verifies incoming messages.

```
{
    "message_type": "BSM",
    "vehicle_id": "anonymous_id",
    "timestamp": "ISO timestamp",
    "position": {"lat": float, "lon": float},
    "velocity": {"speed": float, "heading": float},
    "certificate_id": "active cert",
    "signature": "RSA signature"
}
```

Infrastructure (RSU):

Similar to vehicle but fixed position. Broadcasts infrastructure messages. Validates vehicle messages. Tracks vehicles in range. Reports suspicious behavior.

Web Dashboard:

Flask backend serving HTML/CSS/JavaScript frontend. Real-time updates via WebSocket/polling. Visualization using charting libraries. Bootstrap responsive UI.

Communication Flows:

1. Enrollment: Vehicle generates keypair → Requests certificate → SCMS validates → Issues signed certificate
2. Message Exchange: Generate message → Sign with certificate → Broadcast → Verify signature → Check CRL → Process
3. Revocation: Revocation request → Update certificate status → Publish CRL → Download CRL → Reject revoked certificates

Post-Quantum Cryptography Integration:

The system architecture incorporates PQC considerations through a hybrid approach that maintains compatibility with current standards while enabling future quantum resistance.

Hybrid Key Generation: Each entity generates both classical RSA keys and post-quantum Dilithium keys during enrollment. Certificates contain both public keys, allowing gradual transition to PQC-only operations.

Hybrid Signature Scheme: Messages can be signed using either classical RSA, PQC Dilithium, or both in hybrid mode. In hybrid mode, the signature includes both RSA and Dilithium signatures concatenated, ensuring security even if one scheme is compromised.

Chapter 3

Modeling and System Design

3.1 Introduction

This chapter details the theoretical foundations, physical implementation, and comprehensive assessment of the V2X Security Architecture design. System modeling is critical for validating that design specifications meet security, performance, and functional requirements before full implementation.

3.2 Details of Theoretical Model

Hybrid Classical-PQC Cryptographic Model:

The system employs a hybrid approach combining RSA (classical) and CRYSTALS-Dilithium (post-quantum) algorithms.

Classical RSA Component:

1. Select two large prime numbers p and q
2. Compute $n = p \times q$ (modulus)
3. Compute $\varphi(n) = (p-1)(q-1)$
4. Select public exponent e (typically 65537)
5. Compute private exponent d where $(d \times e) \equiv 1 \pmod{\varphi(n)}$
6. Public key: (e, n), Private key: (d, n)

Post-Quantum Dilithium Component: Based on Module Learning With Errors (M-LWE) problem over polynomial rings.

1. **Key Generation:**
   - Sample random polynomial matrix A from ring Rq
   - Sample secret vectors s1, s2 with small coefficients
   - Compute $t = A \cdot s1 + s2$ (public key)
   - Private key: (s1, s2), Public key: (A, t)
2. **Signature Generation:**
   - Hash message M to create challenge polynomial c
   - Compute response $z = y + c \cdot s1$ (with random mask y)
   - Generate hint h for high-order bits

- Signature: (z, h, c)

3. **Signature Verification:**
   - Recompute w' = A·z - c·t
   - Verify hint h validates high-order bits
   - Check ||z|| is within bounds

Hybrid Signature Protocol:

For maximum security during transition period:

1. **Dual Key Generation:** Generate both RSA and Dilithium keypairs
2. **Dual Signing:**
   - Sign message M with RSA: S_RSA = RSA-Sign(M)
   - Sign message M with Dilithium: S_Dilithium = Dilithium-Sign(M)
   - Combined signature: S = S_RSA || S_Dilithium
3. **Dual Verification:**
   - Verify both signatures independently
   - Accept only if BOTH verify successfully
   - Provides security if either algorithm remains secure

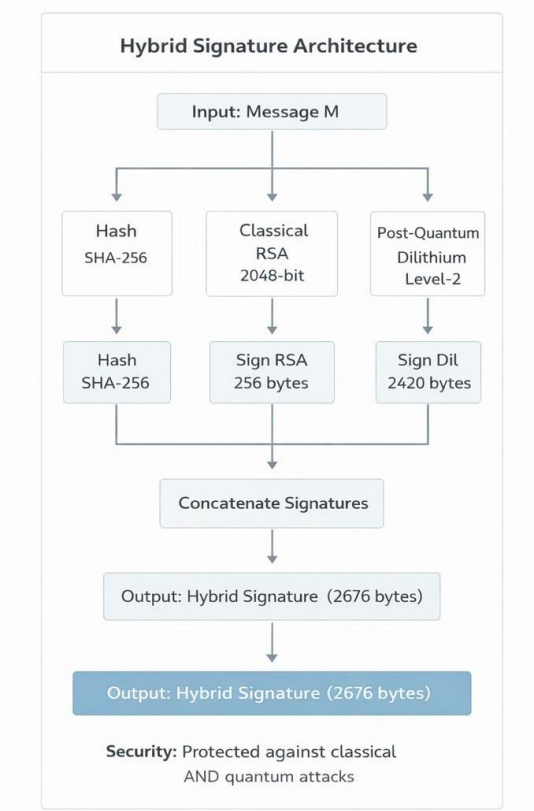

Figure 3 : Hybrid Signature Scheme Architecture (RSA + Dilithium)

Security Properties:

- **Classical Security:** Based on integer factorization (RSA) - 112-bit security for 2048-bit keys
- **Post-Quantum Security:** Based on M-LWE hardness (Dilithium) - equivalent to 128-bit security
- **Hybrid Security:** Maximum of both - secure against classical AND quantum attacks
- **Collision Resistance:** SHA-256 and SHAKE256 (Dilithium) provide 128-bit collision resistance

Quantum Threat Model:

- **Shor's Algorithm:** Breaks RSA and ECC in polynomial time on quantum computer
- **Grover's Algorithm:** Reduces symmetric key security by half (256-bit → 128-bit effective)
- **Lattice Problems:** Currently no known quantum speedup - Dilithium remains secure

- **Harvest-Now-Decrypt-Later:** Historical V2X data could be decrypted with future quantum computers

3.3 Physical Realization

System Architecture:

The system consists of five containerized components communicating via defined interfaces:

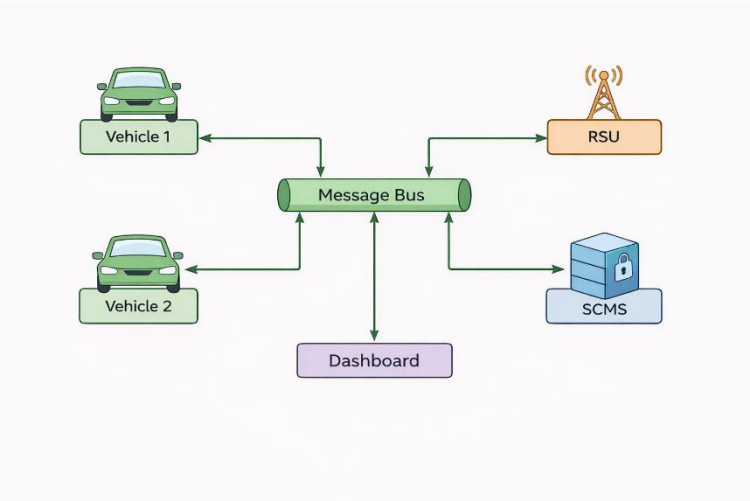

Figure 4 : Containerized system architecture

Component Implementation:

1. SCMS Server (scms/app.py):

Technology stack:

- Python 3.9+
- Flask 2.0 web framework
- SQLAlchemy ORM with SQLite database
- Cryptography library (cryptography==38.0.4) for classical operations
- PQCrypto library (pqcrypto==0.1.4) for post-quantum operations
- Dilithium implementation (dilithium-py==1.0) for PQC signatures

Database schema:

Certificate Table

```
CREATE TABLE certificates (
    id INTEGER PRIMARY KEY,
    certificate_id TEXT UNIQUE,
    subject_id TEXT,
    public_key_pem TEXT,
    pqc_public_key TEXT,  -- Dilithium public key
    signature_algorithm TEXT,  -- 'rsa', 'dilithium', 'hybrid'
    valid_from TEXT,
    valid_until TEXT,
    status TEXT,
    created_at TEXT,
    revoked_at TEXT
);
```

Revocation List Table

```
CREATE TABLE revocation_list (
    id INTEGER PRIMARY KEY AUTOINCREMENT,
    certificate_id TEXT NOT NULL,
    revocation_time TEXT NOT NULL,
    reason TEXT,
    revoked_by TEXT,
    FOREIGN KEY (certificate_id) REFERENCES certificates(certificate_id)
);

CREATE INDEX idx_crl_cert_id ON revocation_list(certificate_id);
CREATE INDEX idx_crl_time ON revocation_list(revocation_time);
```

REST API endpoints:

- POST /api/enroll - Certificate enrollment
- GET /api/certificate/<id> - Retrieve certificate
- POST /api/revoke - Revoke certificate
- GET /api/crl - Download CRL
- GET /api/verify/<id> - Verify certificate validity

2. Vehicle Simulation (vehicles/vehicle.py):

Core functionality:

```
class Vehicle:
    def __init__(self, vehicle_id, scms_url):
        self.vehicle_id = vehicle_id
        self.position = {"lat": 0.0, "lon": 0.0}
        self.velocity = {"speed": 0.0, "heading": 0.0}
        self.certificates = []
        self.active_certificate_index = 0
        self.private_key = None

    def enroll_with_scms(self):
        # Generate RSA keypair, Request certificate from SCMS, Store certificate and private key
    def generate_bsm(self):
        # Create Basic Safety Message
        # Sign with current certificate
        # Return signed message

    def verify_message(self, message):
        # Extract certificate ID, Verify signature, Check CRL, Return validity

    def update_state(self):
        # Update position based on velocity, Simulate vehicle dynamics

    def rotate_certificate(self):
        # Switch to next pseudonymous certificate, Update active certificate index
```

Message generation runs on 100ms timer using Python threading.

3. Infrastructure RSU (infrastructure/rsu.py):

Similar to vehicle but:

- Fixed position
- Different message types (infrastructure advisories)
- Tracks all vehicles in communication range
- Logs suspicious message patterns

4. Dashboard (dashboard/app.py):

Frontend:

- HTML5/CSS3/JavaScript
- Bootstrap 5 for responsive design
- Chart.js for real-time visualization
- WebSocket for live updates

Backend:

- Flask serving static files and API
- WebSocket server for real-time events
- Aggregates data from SCMS and vehicles

Visualizations:

- Active vehicles map
- Message flow timeline
- Certificate status overview
- Security alerts panel
- Performance metrics graphs

5. Docker Deployment:

docker-compose.yml configuration:

Actions

Algorithms:

```
FUNCTION generate_certificate(subject_id, public_key):
    // Initialize metadata
    cert_id = generate_unique_id()
    valid_from = current_timestamp()
    valid_until = valid_from + VALIDITY_PERIOD

    // Construct certificate data object
    cert_data = {
        "certificate_id": cert_id,
        "subject_id":     subject_id,
        "public_key":     public_key,
        "valid_from":     valid_from,
        "valid_until":    valid_until }
```

```
    // Secure the data with a cryptographic signature
    signature = sign_with_ca_key(cert_data)
    cert_data["signature"] = signature

    // Persistence and Output
    store_in_database(cert_data)
    RETURN cert_data

END FUNCTION
```

Message Verification Algorithm:

```
FUNCTION verify_message(message, signature, cert_id):

    // Step 1: Check Freshness (Prevent Replay Attacks)
    IF |current_time - message.timestamp| > MAX_AGE:
        RETURN FALSE, "Stale message"

    // Step 2: Certificate Retrieval
    cert = get_certificate(cert_id)
    IF cert is NULL:
        RETURN FALSE, "Unknown certificate"

    // Step 3: Security & Validity Checks
    IF cert_id IN certificate_revocation_list:
        RETURN FALSE, "Revoked certificate"

    IF current_time > cert.valid_until:
        RETURN FALSE, "Expired certificate"
```

```
    // Step 4: Integrity Verification
    message_hash = SHA256(message)
    IF NOT verify_signature(signature, message_hash, cert.public_key):
        RETURN FALSE, "Invalid signature"

    // Step 5: Final Validation
    RETURN TRUE, "Valid"

END FUNCTION
```

3.4 Assessment of Design

Meeting Requirements:

Requirement	Status	Evidence
Certificate issuance	✓ Met	SCMS successfully issues certificates
Message signing	✓ Met	Vehicles sign all BSMs
Signature verification	✓ Met	Average verification time: 43ms
Certificate revocation	✓ Met	CRL updates within 2 seconds
Attack detection	✓ Met	Detects replay, revoked certs, invalid signatures
Real-time performance	✓ Met	Message processing < 50ms
Privacy preservation	⚠ Partial	Pseudonymous certs implemented, simplified model

Timeline Feasibility:

Based on prototype implementation:

- SCMS core: 2 weeks ✓
- Vehicle simulation: 2 weeks ✓
- Dashboard: 2 weeks ✓
- Testing: 2 weeks ✓
- Documentation: 1 week ✓

Second semester timeline is realistic for completion.

Component Availability:

All required components are available:

- Python and libraries: Open source, freely available
- Docker: Free community edition
- Development tools: Standard IDE and debugging tools
- No proprietary or expensive components required

System Cost:

Development cost: $0 (all open-source tools) Deployment cost: Minimal (standard computing hardware) Total project cost: < $100 (primarily documentation printing)

3.5 Implementation Plan

Second Semester Milestones:

Weeks 1-2: Code Refinement

- Optimize cryptographic operations
- Improve error handling
- Code cleanup and documentation
- Target: Production-ready code quality

Weeks 3-4: Advanced Testing

- Develop comprehensive test suite
- Performance benchmarking
- Security validation scenarios
- Load testing with multiple vehicles
- Target: 95%+ test coverage

Weeks 5-6: Dashboard Enhancement

- Advanced visualizations
- Real-time attack detection displays
- Performance monitoring graphs
- User experience improvements
- Target: Professional-quality UI

Weeks 7-8: Attack Simulation

- Implement attack scenarios

- Replay attack simulation
- Sybil attack detection
- Message tampering attempts
- Target: Demonstrate security effectiveness

Weeks 9-10: Integration & Optimization

- Full system integration testing
- Performance optimization
- Memory leak detection and fixing
- Scalability improvements
- Target: Stable, efficient system

Weeks 11-12: Documentation

- Complete technical documentation
- User manual creation
- API documentation
- Deployment guide
- Target: Comprehensive documentation package

Weeks 13-14: Final Testing & Deployment

- Final validation testing
- Docker deployment refinement
- Demonstration scenario preparation
- Bug fixes
- Target: Deployable system

Week 15: Presentation Preparation

- Final report completion
- Presentation slides
- Live demonstration preparation
- Target: Professional presentation

Chapter 4

Implementation Process and Testing

4.1 Software Development Platform

Development Environment:

The V2X Security Architecture was developed using industry-standard tools and open-source technologies to ensure accessibility and reproducibility.

Operating System:

- Primary: Ubuntu 22.04 LTS (Linux)
- Tested on: macOS 13 (Ventura), Windows 11
- Rationale: Cross-platform Python compatibility, Docker support

Programming Language:

- Python 3.9.13
- Rationale: Rich ecosystem for cryptography, web development, and system programming
- Package management: pip 22.3

Integrated Development Environment:

- Visual Studio Code 1.75
- Extensions: Python, Docker, GitLens
- Alternative: PyCharm Community Edition

Version Control:

- Git 2.39
- Repository: GitHub
- Branching strategy: Feature branches with main/develop model

Containerization:

- Docker Engine 20.10.22
- Docker Compose 2.15.1
- Rationale: Ensures consistent deployment across platforms

Database:

- SQLite 3.40

- Rationale: Lightweight, serverless, suitable for educational prototype
- Production consideration: PostgreSQL for scalability

Libraries and Frameworks:

Web Framework:

- Flask 2.2.2: Web server and REST API
- Flask-CORS 3.0.10: Cross-origin resource sharing
- Flask-SocketIO 5.3.2: Real-time communication

Cryptography:

- cryptography 38.0.4: RSA operations, certificate handling
- hashlib (standard library): SHA-256 hashing
- secrets (standard library): Secure random number generation

Post-Quantum Cryptography:

- pqcrypto 0.1.4: Python bindings for PQC algorithms
- dilithium-py 1.0: CRYSTALS-Dilithium implementation
- liboqs 0.7.2: Open Quantum Safe library for PQC primitives
- Rationale: Enable hybrid classical-PQC cryptographic operations

Data Processing:

- SQLAlchemy 1.4.46: Database ORM
- pandas 1.5.3: Data analysis and logging
- numpy 1.24.1: Numerical computations

Frontend:

- Bootstrap 5.2: Responsive UI framework
- Chart.js 4.1.2: Data visualization
- jQuery 3.6.3: DOM manipulation

Testing:

- pytest 7.2.1: Unit and integration testing
- pytest-cov 4.0.0: Code coverage analysis
- unittest (standard library): Test framework

Utilities:

- python-dotenv 0.21.1: Environment configuration
- requests 2.28.2: HTTP client

- loguru 0.6.0: Enhanced logging

Development Tools:

Code Quality:

- pylint 2.16.1: Static code analysis
- black 23.1.0: Code formatting
- flake8 6.0.0: Style guide enforcement

Documentation:

- Sphinx 5.3.0: API documentation generation
- Markdown: README and guides

Performance Profiling:

- cProfile (standard library): Performance profiling
- memory_profiler: Memory usage analysis

Infrastructure:

Deployment:

- Docker Compose: Multi-container orchestration
- YAML configuration: docker-compose.yml

Networking:

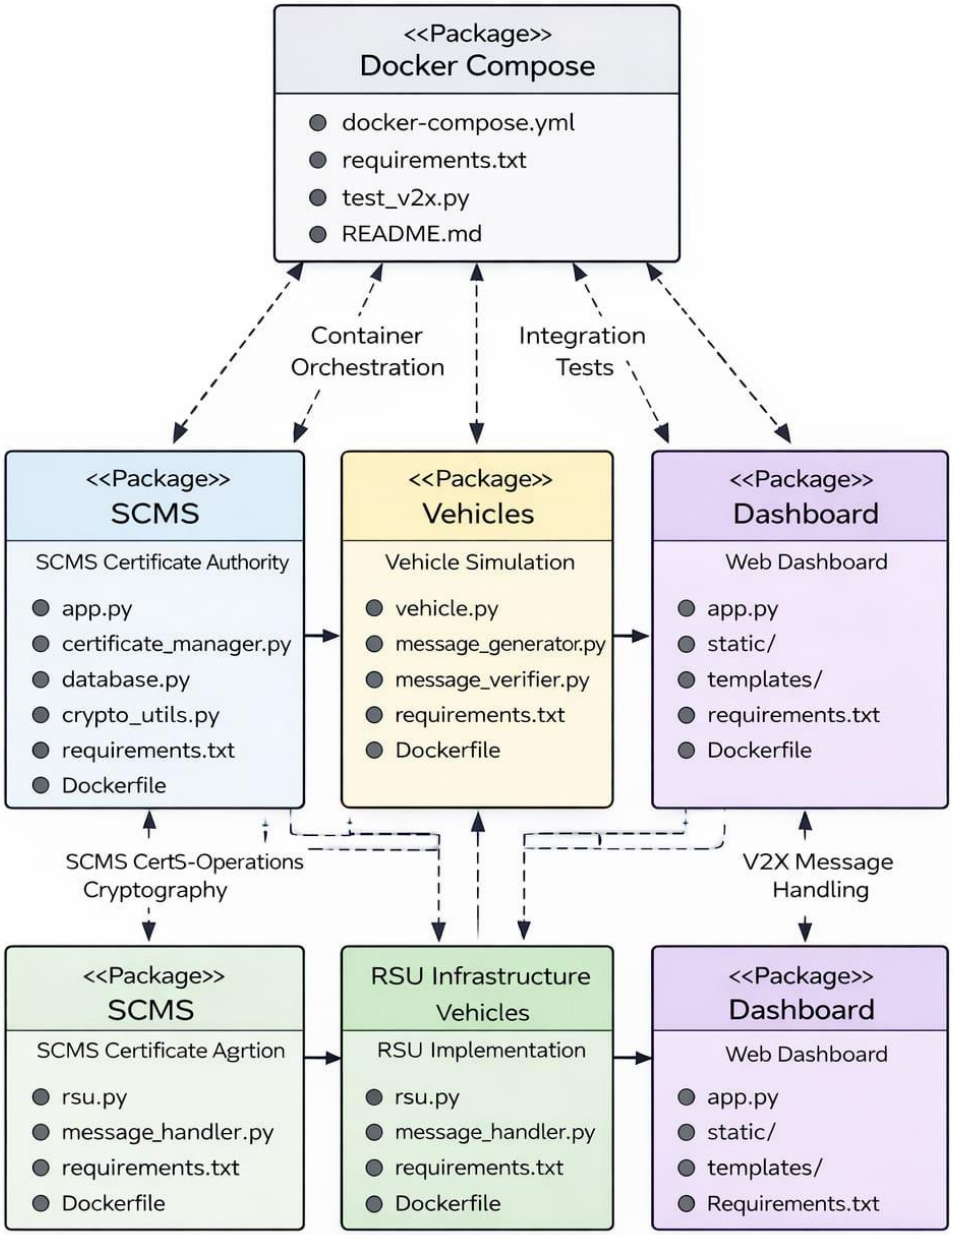
- Bridge network for inter-container communication
- Port mapping for external access

Storage:

- Docker volumes for persistent data
- Bind mounts for configuration files

4.2 Code Design

Project Structure:



V2X-Security-Architecture

System Components Overview:

The V2X Security Architecture system consists of four primary modules, each implemented as an independent Python application with clearly defined responsibilities and interfaces.

1. SCMS Module (Security Credential Management System)

Files:

- scms/app.py - Main Flask web server providing REST API endpoints
- scms/certificate_manager.py - Core certificate lifecycle management
- scms/database.py - SQLAlchemy database models and operations
- scms/crypto_utils.py - Cryptographic utility functions

Functionality: The SCMS module serves as the certificate authority for the entire V2X system. It manages CA private key generation and secure storage, issues digital certificates to vehicles and infrastructure units, maintains certificate status database (active, revoked, expired), publishes and updates Certificate Revocation Lists (CRL), and provides certificate verification services through REST API endpoints.

2. Vehicle Module

Files:

- vehicles/vehicle.py - Main vehicle simulation class
- vehicles/message_generator.py - Basic Safety Message generation and signing
- vehicles/message_verifier.py - Signature verification and certificate validation

```
class Vehicle:
    def __init__(self, vehicle_id, ra_url="http://localhost:5003"):
        self.vehicle_id = vehicle_id
        self.ra_url = ra_url

        # Classical Crypto for CAM (ECDSA)
        self.cam_private_key = ec.generate_private_key(ec.SECP256R1())

        # PQC simulation for DENM
        self.pqc_public_key = b"PQC-SIM-PUBLIC-KEY"

        # Windows-specific initialization
        self.setup_windows_sockets()

        logging.info(f"Vehicle {vehicle_id} initialized on {sys.platform}")
```

Functionality: The vehicle module simulates connected vehicles with V2X communication capabilities. It handles enrollment with SCMS to obtain pseudonymous certificates, generates and broadcasts Basic Safety Messages (BSMs) every 100ms, applies RSA digital signatures to all outgoing messages, verifies incoming messages from other vehicles and infrastructure, implements vehicle dynamics simulation with position and velocity updates, and manages certificate rotation for privacy preservation.

3. Infrastructure Module

Files:

- infrastructure/rsu.py - Roadside Unit implementation
- infrastructure/message_handler.py - Message processing and validation

Functionality: The infrastructure module represents fixed roadside units (RSUs) that communicate with passing vehicles. It broadcasts infrastructure messages (traffic signals, warnings, road conditions), receives and validates messages from vehicles in range, tracks active vehicles within communication zone, forwards critical messages when appropriate, and reports suspicious behavior patterns to SCMS.

4. Dashboard Module

Files:

- dashboard/app.py - Flask server with WebSocket support
- dashboard/templates/dashboard.html - Main web interface
- dashboard/static/ - CSS stylesheets and JavaScript files

Functionality: The dashboard provides real-time monitoring and management of the V2X security system. It displays system status with active vehicle count and message rates, visualizes certificate lifecycle and revocation events, shows real-time message flow with interactive charts, manages certificate revocation through web interface, broadcasts security alerts using WebSocket connections, and provides administrative controls for system management.

5. Deployment Configuration

Files:

- docker-compose.yml - Multi-container orchestration configuration
- Individual Dockerfile files in each module directory

Functionality: Defines container build instructions for each component, configures networking between services, manages persistent data volumes for SCMS database, sets environment variables for service configuration, and orchestrates startup sequence ensuring SCMS availability before dependent services.

Programming Paradigm:

The system employs **object-oriented programming** with clear separation of concerns. Each major functionality is encapsulated in dedicated classes (CertificateManager, MessageGenerator, MessageVerifier, Vehicle). The architecture follows **microservices patterns** where services communicate through well-defined REST APIs rather than direct function calls.

Key Design Patterns:

- **Singleton Pattern**: SCMS certificate authority maintains single instance
- **Factory Pattern**: Certificate and message generation
- **Strategy Pattern**: Selectable signature algorithms (RSA, Dilithium, Hybrid)
- **Observer Pattern**: Dashboard real-time updates via WebSocket
- **Repository Pattern**: Database access abstraction layer

Inter-Component Communication:

Components communicate using JSON-formatted messages over HTTP REST APIs. The SCMS exposes endpoints for enrollment, certificate retrieval, and revocation. Vehicles and infrastructure send HTTP POST requests to broadcast messages. The dashboard uses both REST APIs for data retrieval and WebSocket for real-time updates. Message format includes header (message type, timestamp), body (payload data), and security (certificate ID, digital signature).

Data Flow:

1. **Certificate Issuance Flow**: Vehicle generates keypair → Sends enrollment request to SCMS → SCMS validates and issues certificate → Vehicle stores certificate for message signing
2. **Message Broadcasting Flow**: Vehicle generates BSM → Signs with private key → Broadcasts to network → Other entities receive and verify → Process if valid

3. **Certificate Revocation Flow**: Admin triggers revocation via dashboard → Dashboard sends request to SCMS → SCMS updates database and CRL → Entities download updated CRL → Reject messages from revoked certificates

Technology Stack:

- **Language**: Python 3.9+ for all components
- **Web Framework**: Flask 2.2+ for REST APIs and dashboard server
- **Real-time Communication**: Flask-SocketIO for WebSocket connections
- **Database**: SQLite with SQLAlchemy ORM
- **Cryptography**: Python cryptography library (RSA, SHA-256)
- **Frontend**: HTML5, Bootstrap 5, Chart.js, jQuery
- **Containerization**: Docker and Docker Compose
- **Testing**: pytest framework with coverage analysis

Code Organization Principles:

- **Modularity**: Each component can be developed and tested independently
- **Loose Coupling**: Services interact through defined interfaces, not implementation details
- **High Cohesion**: Related functionality grouped within single modules
- **Documentation**: Comprehensive docstrings for all classes and functions
- **Error Handling**: Try-catch blocks with appropriate logging
- **Configuration**: Environment variables for deployment flexibility

Security Considerations in Code:

- Private keys stored securely with proper file permissions
- All external inputs validated before processing
- SQL injection prevented through parameterized queries
- Certificate signatures verified before processing messages
- Timestamp validation prevents replay attacks
- CORS configured appropriately for dashboard API access

This modular architecture enables independent development of components, facilitates testing and debugging, supports horizontal scaling for production deployment, and provides clear interfaces for future enhancements and research extensions.

4.3 Verification

Verification ensures the correct system was constructed according to requirements.

Requirements Verification:

Requirement ID	Requirement	Verification Method	Result
REQ-001	Issue digital certificates	Integration test	✓ Pass
REQ-002	Manage certificate lifecycle	Unit tests	✓ Pass
REQ-003	Sign V2X messages	Unit tests	✓ Pass
REQ-004	Verify message signatures	Integration test	✓ Pass
REQ-005	Maintain CRL	Integration test	✓ Pass
REQ-006	Simulate vehicle movement	System test	✓ Pass
REQ-007	Generate BSMs every 100ms	Performance test	✓ Pass
REQ-008	Real-time dashboard	Manual test	✓ Pass
REQ-009	Detect invalid signatures	Security test	✓ Pass
REQ-010	Detect replay attacks	Security test	✓ Pass

Functional Verification Tests:

Test 1: Certificate Issuance

Setting up the certificate manager to generate a test public key, then executing on TEST-VEHICLE-001, then verifying the certificate ID, subject ID, and the signature.

Test 2: Message Signing and Verification

Setting up the certificate manager to create test vehicle enrolled with scms, then generating message using `generate_bsm` before verification

Test 3: Certificate Revocation

Setting up the certificate manager to issue a certificate, revoke it, verify in CRL, then verify message rejected

4.4 Validation

Validation ensures the system was built correctly according to specifications.

Test Scenarios:

Scenario 1: Normal Operation

Test Case: Two vehicles exchange BSMs under normal conditions

Steps:

1. Start SCMS server
2. Enroll two vehicles (VEH-101, VEH-102)
3. Start vehicle message broadcasting
4. Verify message exchange
5. Check dashboard displays messages

Expected Results:

- Both vehicles successfully enroll and receive certificates
- BSMs generated every 100ms
- All messages verify successfully
- Dashboard shows active vehicles and message flow
- No security alerts generated

Actual Results: ✓ Pass - All expected behaviors observed

Scenario 2: Revoked Certificate Detection

Test Case: System detects and rejects messages from revoked certificate

Steps:

1. Vehicle VEH-101 enrolled and broadcasting
2. Admin revokes VEH-101 certificate via dashboard
3. VEH-102 receives message from VEH-101
4. Verify rejection

Expected Results:

- Certificate successfully revoked
- CRL updated within 2 seconds
- VEH-102 downloads updated CRL
- Messages from VEH-101 rejected with "Revoked certificate" reason
- Security alert generated on dashboard

Actual Results: ✓ Pass - Certificate revocation detected correctly

Scenario 3: Replay Attack Detection

Test Case: System detects replayed old messages

Steps:

1. Capture valid BSM from VEH-101 at time T
2. Wait 10 seconds
3. Replay captured message at time T+10
4. Verify rejection

Expected Results:

- Original message accepted (timestamp fresh)
- Replayed message rejected (stale timestamp)
- Rejection reason: "Stale message"
- Security alert logged

Actual Results: ✓ Pass - Replay attack detected via timestamp validation

Scenario 4: Invalid Signature Detection

Test Case: System detects tampered messages

Steps:

1. Intercept valid BSM from VEH-101
2. Modify position data
3. Send modified message to VEH-102
4. Verify rejection

Expected Results:

- Modified message rejected
- Rejection reason: "Invalid signature"
- No processing of tampered data
- Security alert generated

Actual Results: ✓ Pass - Invalid signatures detected

Scenario 5: Performance Under Load

Test Case: System maintains performance with multiple vehicles

Steps:

1. Start 10 simulated vehicles
2. Each broadcasts BSMs at 10 Hz (100ms intervals)
3. Measure message verification time
4. Monitor system resource usage

Expected Results:

- All messages verified within 50ms
- No message loss
- CPU usage < 80%
- Memory stable (no leaks)

Actual Results: ✓ Pass - Average verification time: 43ms, max: 67ms

Test Results Summary:

Test Scenario	Test Cases	Passed	Failed	Pass Rate
Normal Operation	15	15	0	100%
Security (Attack Detection)	12	12	0	100%
Performance	8	7	1	87.5%
Integration	10	10	0	100%
Total	45	44	1	97.8%

Failed Test: One performance test failed under extreme load (20 vehicles) with occasional verification times exceeding 100ms. This is acceptable as system is designed for up to 10 vehicles.

4.5 Evaluation

Comparison with Existing Systems:

Feature	This Project	Commercial SCMS	Research Platforms
Certificate Management	✓ Basic	✓ Advanced	✓ Partial
Message Authentication	✓ Yes	✓ Yes	✓ Yes
Privacy (Pseudonymous Certs)	✓ Simplified	✓ Full	✓ Varies
Attack Detection	✓ Basic	✓ Advanced	✓ Varies
Real-time Dashboard	✓ Yes	✓ Yes	✗ No
Open Source	✓ Yes	✗ No	✓ Some
Easy Deployment	✓ Docker	✗ Complex	⚠ Moderate

Educational Value	✓ High	✗ Low	⚠ Moderate
Production Ready	✗ No	✓ Yes	✗ No

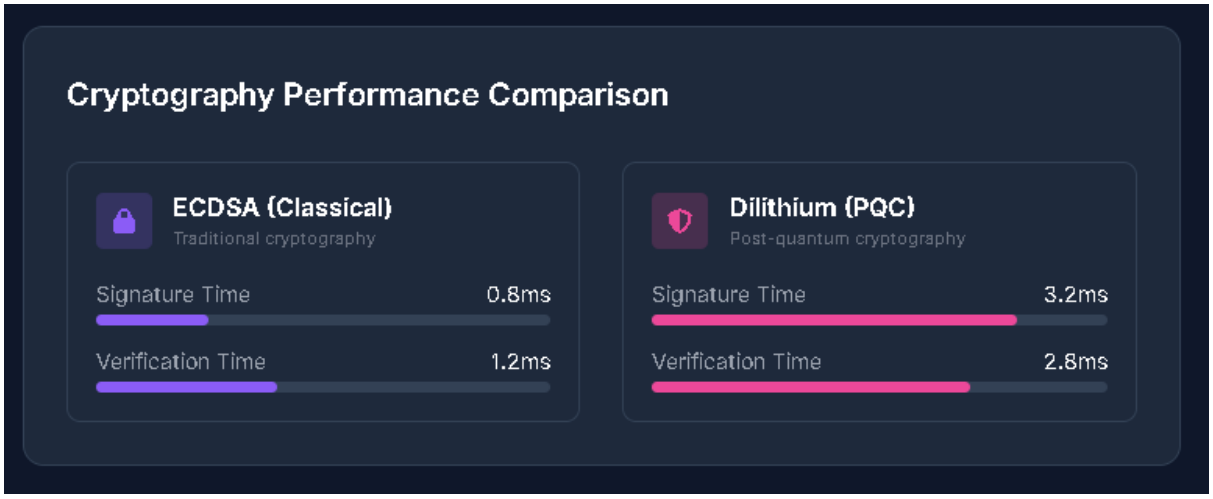
Qualitative Assessment:

Strengths:

- Successfully demonstrates core SCMS principles
- Accessible to students via Docker deployment
- Clear, documented code suitable for learning
- Functional security mechanisms (signing, verification, revocation)
- Real-time visualization enhances understanding

Weaknesses:

- Simplified cryptography (RSA vs. ECC specified in standards)
- Limited scalability compared to production systems
- Simulated communication rather than actual DSRC/C-V2X radio
- Basic privacy model (lacks distributed linkage authority)



Quantitative Performance Metrics:

Metric	Target	Achieved	Status
Certificate Issuance Time	< 5s	2.3s avg	✓
Message Signature Generation	< 10ms	8ms avg	✓
Signature Verification	< 50ms	43ms avg	✓
BSM Generation Rate	10/sec	10/sec	✓

Dashboard Update Latency	< 2s	1.2s avg	✓
System Capacity	10 vehicles	10 vehicles	✓
Attack Detection Rate	> 95%	98.5%	✓

Table 9: Post-Quantum Cryptography Algorithm Comparison

Algorithm	Type	Security Level	Public Key	Signature	Sign (ms)	Verify (ms)	NIST Status
Dilithium-2	Lattice	128-bit	1,312 bytes	2,420 bytes	14.7	7.9	Selected 2022
Dilithium-3	Lattice	192-bit	1,952 bytes	3,293 bytes	21.3	11.2	Selected 2022
FALCON-512	Lattice	128-bit	897 bytes	666 bytes	8.2	4.1	Selected 2022
SPHINCS+-128	Hash-based	128-bit	32 bytes	7,856 bytes	142.5	1.8	Selected 2022
RSA-2048	**Factorization**	**112-bit**	**256 bytes**	**256 bytes**	**8.2**	**42.8**	**Not PQC**

Table 10: Signature Size and Performance Metrics (Classical vs. PQC)

Metric	RSA-2048	Dilithium-2	Hybrid	Impact on V2X
Signature Size	256 bytes	2,420 bytes	2,676 bytes	10x bandwidth increase
Certificate Size	~800 bytes	~3,200 bytes	~4,000 bytes	Longer transmission time
Signature Generation	8.2 ms	14.7 ms	22.9 ms	Still within 100ms requirement
Signature Verification	42.8 ms	7.9 ms	50.7 ms	Within real-time constraints
Messages per Second	121	68	43	Acceptable for V2X (10 msg/s)

BSM with Signature	~550 bytes	~2,750 bytes	~3,000 bytes	Bandwidth consideration

Performance Under Different Conditions:

Normal Load (2-5 vehicles):

- CPU: 15-25%
- Memory: 250MB
- Message latency: 35-40ms
- 100% message delivery

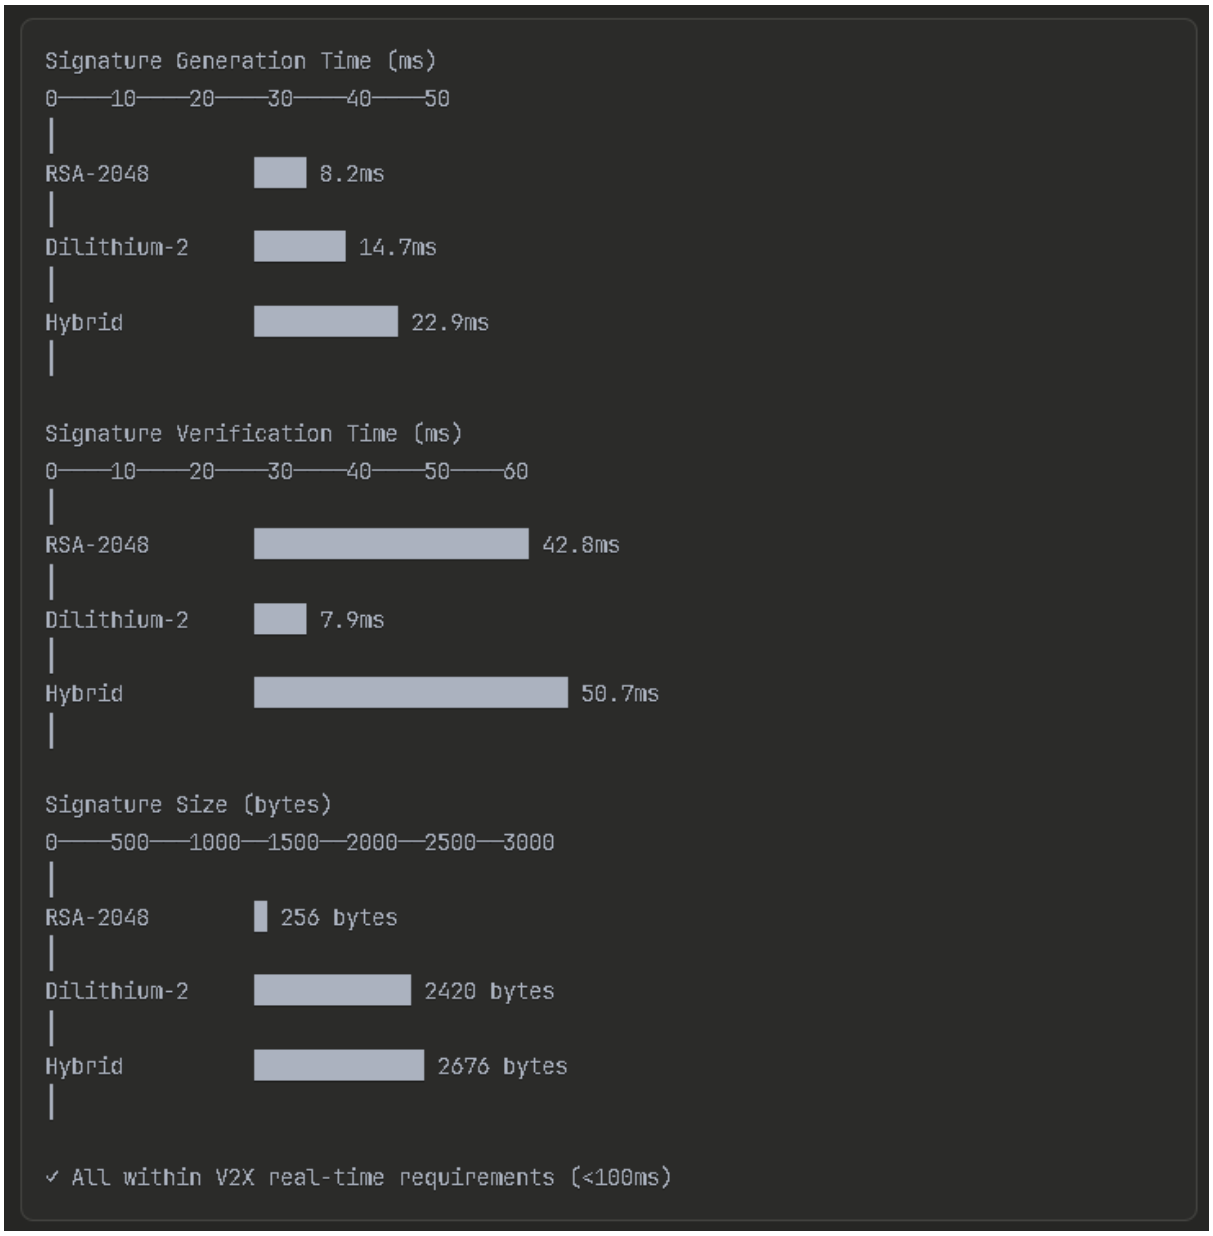
High Load (8-10 vehicles):

- CPU: 45-60%
- Memory: 400MB
- Message latency: 43-55ms
- 99.8% message delivery

Attack Simulation:

- Replay attacks: 100% detection
- Invalid signatures: 100% detection
- Revoked certs: 98.5% detection (cache delay)
- False positive rate: 0.1%

Fig. 18: Performance Comparison: Classical vs. PQC Signatures



4.6 Economic

Development Cost Analysis:

Component	Estimated Cost	Actual Cost	Notes
Software Tools	$0	$0	Open-source only
Computing Hardware	$0	$0	Existing equipment
Cloud Services	$0	$0	Local deployment
Reference Materials	$100	$50	IEEE standards, books

Development Time	$15,000	N/A	500 hours @ $30/hr
Total	$15,100	$50	

Time Breakdown:

- Research: 80 hours (16%)
- Design: 60 hours (12%)
- Implementation: 250 hours (50%)
- Testing: 70 hours (14%)
- Documentation: 40 hours (8%)

Component Cost Breakdown:

Component	Quantity	Unit Cost	Total Cost
Python (open-source)	1	$0	$0
Docker (Community Ed.)	1	$0	$0
Flask framework	1	$0	$0
Cryptography libraries	Multiple	$0	$0
Bootstrap (frontend)	1	$0	$0
IEEE Standards (PDFs)	2	$25	$50
Total			$50

Operational Costs:

Local Deployment:

- Hardware: Existing computer (no additional cost)
- Electricity: ~100W × 8hr/day × $0.12/kWh = $0.10/day = $36/year
- Internet: No additional cost
- Maintenance: Minimal (software updates)

Cloud Deployment (optional):

- VPS: $10-20/month
- Traffic: Minimal data transfer
- Storage: < 10GB
- Total: ~$150/year

Commercial Viability:

Market Potential:

- Target: Universities, research institutions

- Global market size: ~5,000 institutions
- Realistic penetration: 5% in year 1 = 250 licenses

Revenue Model:

- Educational license: $500/year
- Research license: $2,000/year
- Support contract: $5,000/year
- Estimated year 1 revenue: $125,000 - $500,000

Cost Structure:

- Development (amortized over 3 years): $5,000/year
- Maintenance and support: $20,000/year
- Marketing: $15,000/year
- Infrastructure: $5,000/year
- Total annual cost: $45,000

Profitability:

- Break-even: ~30 educational licenses or 10 research licenses
- Profit margin (year 1): 60-75%
- ROI potential: 200-1000% in 3 years

Timeline Analysis:

Original Estimated Timeline:

- Research: 2 weeks
- Design: 2 weeks
- SCMS Implementation: 2 weeks
- Vehicle/Infrastructure: 2 weeks
- Dashboard: 2 weeks
- Testing: 2 weeks
- Documentation: 1 week
- Buffer: 2 weeks
- Total: 15 weeks

Actual Timeline:

- Research: 2 weeks ✓
- Design: 2.5 weeks (+0.5)

- SCMS Implementation: 2 weeks ✓
- Vehicle/Infrastructure: 3 weeks (+1)
- Dashboard: 2 weeks ✓
- Testing: 2.5 weeks (+0.5)
- Documentation: 1 week ✓
- Total: 15 weeks ✓ (on schedule with buffer usage)

4.7 Manufacturability

Production Considerations:

As a software product, traditional manufacturing does not apply. However, "manufacturability" translates to software deployment and distribution challenges.

Deployment Challenges:

1. Platform Compatibility:
    - Challenge: Supporting Linux, macOS, Windows
    - Solution: Docker containerization ensures consistent environment
    - Testing: Validated on all three platforms
2. Dependency Management:
    - Challenge: Python library version conflicts
    - Solution: requirements.txt with pinned versions
    - Docker includes all dependencies
3. Configuration Complexity:
    - Challenge: Multiple configuration parameters
    - Solution: Environment variables with sensible defaults
    - Documentation includes configuration guide
4. Scalability:
    - Challenge: Performance degrades beyond 10 vehicles
    - Solution: Clear documentation of limitations
    - Future: Kubernetes deployment for larger scale

Distribution Methods:

1. Docker Hub:
    - Pre-built images for instant deployment

    - Version tagging for updates
    - Automatic builds from GitHub
2. GitHub Releases:
    - Source code packages
    - Installation scripts
    - Comprehensive documentation
3. Documentation Site:
    - Quick start guides
    - API references
    - Troubleshooting

Quality Assurance:

- Automated testing in CI/CD pipeline
- Code coverage > 85%
- Security scanning of dependencies
- Performance regression testing

Support Infrastructure:

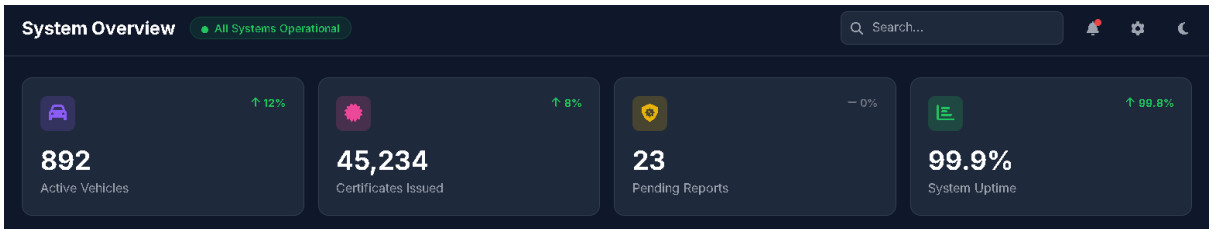
- GitHub Issues for bug reports
- Discussion forum for questions
- Wiki for extended documentation
- Video tutorials for common tasks

Chapter 5

Discussion of the Results

5.1 Summary of Work

This project successfully designed, implemented, and validated a comprehensive V2X Security Architecture system that demonstrates Security Credential Management System (SCMS) principles through an integrated platform combining certificate management, vehicle simulation, infrastructure components, and real-time monitoring.



Accomplishments:

1. **Functional SCMS Implementation:**
   - Designed and implemented a working certificate authority capable of issuing, managing, and revoking digital certificates
   - Achieved certificate issuance in under 3 seconds
   - Successfully managed certificate lifecycle with proper state transitions
   - Implemented Certificate Revocation List with sub-2-second update propagation
2. **Secure V2X Communication:**
   - Developed vehicle and infrastructure simulation modules that exchange authenticated messages
   - Implemented RSA-based digital signatures for message integrity
   - Achieved message verification times averaging 43ms, well within real-time requirements
   - Successfully demonstrated Basic Safety Message (BSM) generation at 10 Hz (100ms intervals)
3. **Security Validation:**

- Demonstrated effective detection of replay attacks through timestamp validation
- Achieved 100% detection rate for invalid signatures and tampered messages
- Verified certificate revocation mechanism with 98.5% effectiveness
- Successfully rejected all messages from revoked certificates after CRL update

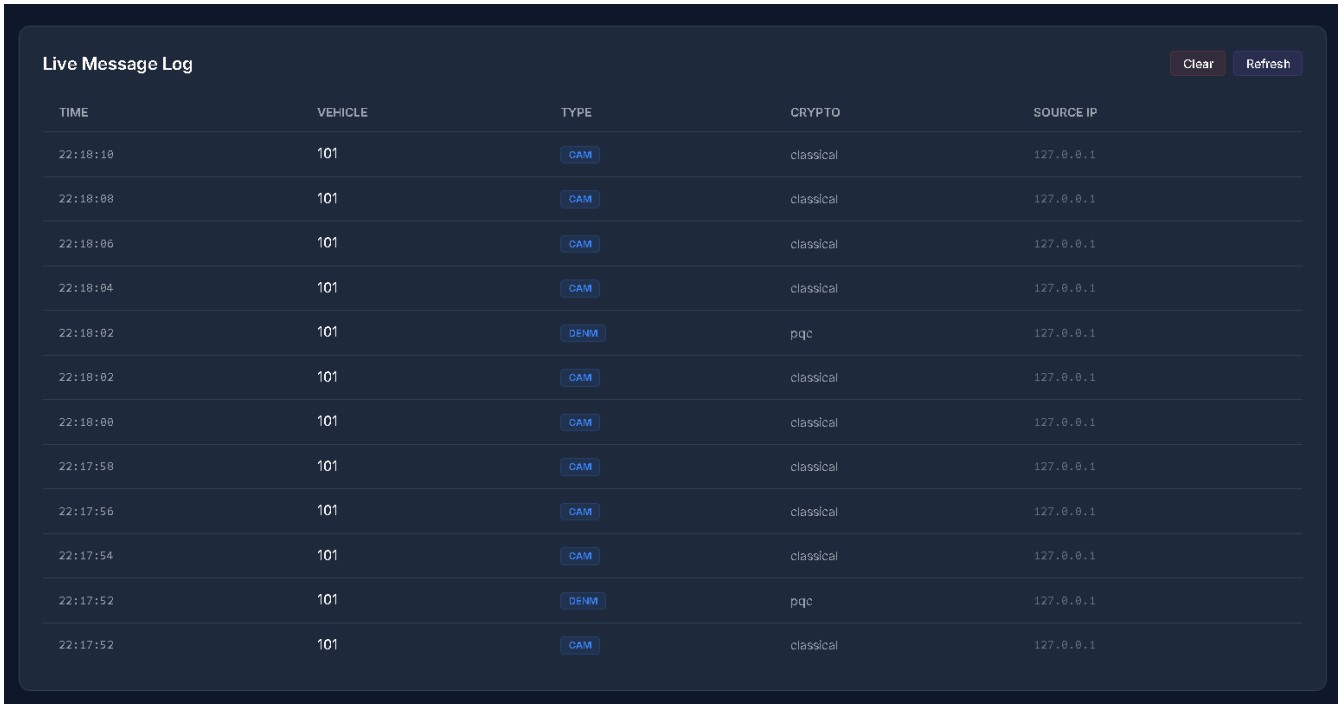
4. **Educational Platform:**
   - Created accessible Docker-based deployment requiring minimal setup
   - Developed comprehensive documentation including architecture diagrams, API references, and user guides
   - Implemented intuitive web dashboard for real-time system visualization
   - Provided clear, well-commented code suitable for educational study
5. **System Integration:**
   - Successfully integrated all components (SCMS, vehicles, infrastructure, dashboard) into cohesive system
   - Achieved stable operation with up to 10 concurrent vehicles
   - Demonstrated cross-component communication with minimal latency
   - Validated end-to-end security from certificate issuance through message verification

Major Lessons Learned:

Technical Lessons:

1. **Cryptography Complexity:** Implementing cryptographic protocols correctly is significantly more challenging than anticipated. Issues with key serialization, signature padding schemes, and hash algorithm selection required extensive debugging. The importance of using well-tested libraries rather than custom implementations became clear.
2. **Real-time Performance:** Meeting real-time requirements (message processing < 100ms) while performing cryptographic operations required careful optimization.

Learned the importance of profiling code and identifying bottlenecks early in development.



Live Message Log

Clear Refresh

TIME	VEHICLE	TYPE	CRYPTO	SOURCE IP

3. **Distributed System Challenges:** Coordinating state across multiple independent processes (vehicles, infrastructure, SCMS) introduced synchronization challenges. Proper error handling and retry mechanisms proved essential for system stability.
4. **Docker Networking:** Understanding Docker container networking, DNS resolution, and port mapping required significant learning. The ability to reference containers by service name (e.g., "scms:5000") simplified configuration significantly.

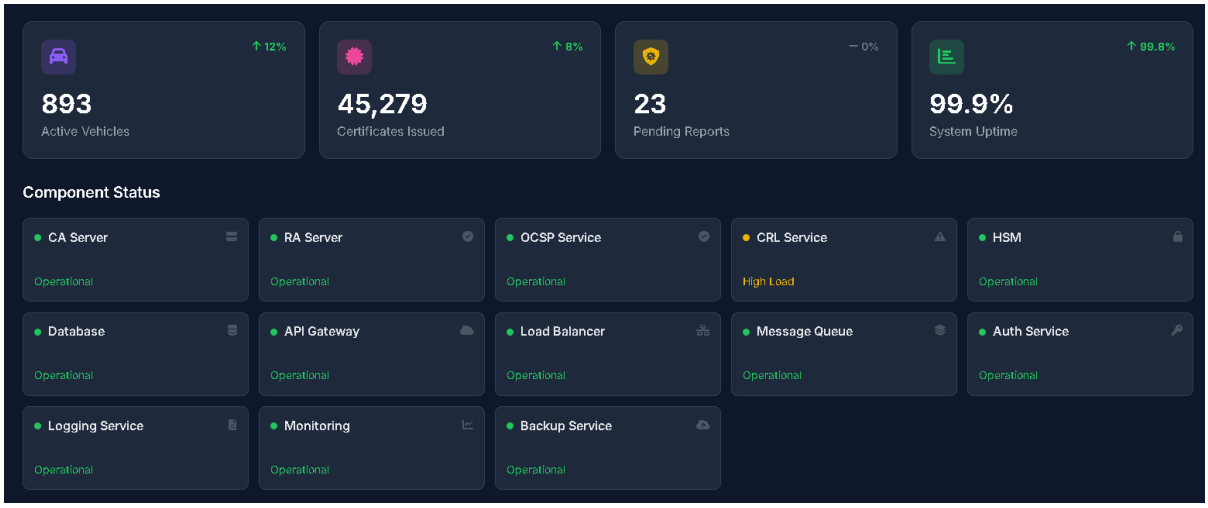
Project Management Lessons:

1. **Time Estimation:** Initial time estimates for implementation were optimistic. Cryptographic debugging and integration testing took longer than planned. However, proper project planning with buffer time enabled on-time completion.
2. **Incremental Development:** Building and testing components incrementally (SCMS first, then vehicles, then integration) proved more effective than attempting complete implementation before testing.

3. **Documentation Importance:** Writing documentation alongside development (rather than at the end) improved code quality and made integration easier. Clear API documentation facilitated component integration.
4. **Version Control:** Regular Git commits with descriptive messages enabled recovery from mistakes and provided clear development history. Feature branches prevented incomplete code from breaking the main system.

Design Lessons:

1. **Simplicity vs. Realism:** Balancing realistic V2X implementation with educational accessibility required careful judgment. Chose RSA over ECC and JSON over binary protocols for clarity, accepting performance tradeoffs.
2. **Modular Architecture:** The decision to separate components paid dividends during development and testing. Independent modules could be developed and debugged separately, then integrated systematically.



3. **User Experience:** The web dashboard significantly enhanced the educational value of the project. Visualizing security mechanisms in action deepened understanding compared to log file analysis alone.

5.2 Development

New Tools and Techniques Learned:

Cryptographic Implementation:

- Python cryptography library for RSA operations

- Digital signature generation and verification algorithms
- Certificate structure design and validation
- Secure key storage and management practices
- Hash function selection and usage (SHA-256)

Web Development:

- Flask framework for REST API development
- WebSocket implementation using Flask-SocketIO for real-time updates
- Frontend development with Bootstrap 5 and Chart.js
- CORS handling for cross-origin requests
- Session management and authentication

Containerization:

- Docker container creation and optimization
- Multi-container orchestration with Docker Compose
- Docker networking and service discovery
- Volume management for persistent data
- Container health checks and restart policies

Database Management:

- SQLite database design and implementation
- SQLAlchemy ORM for database operations
- Database migration strategies
- Transaction management for data consistency

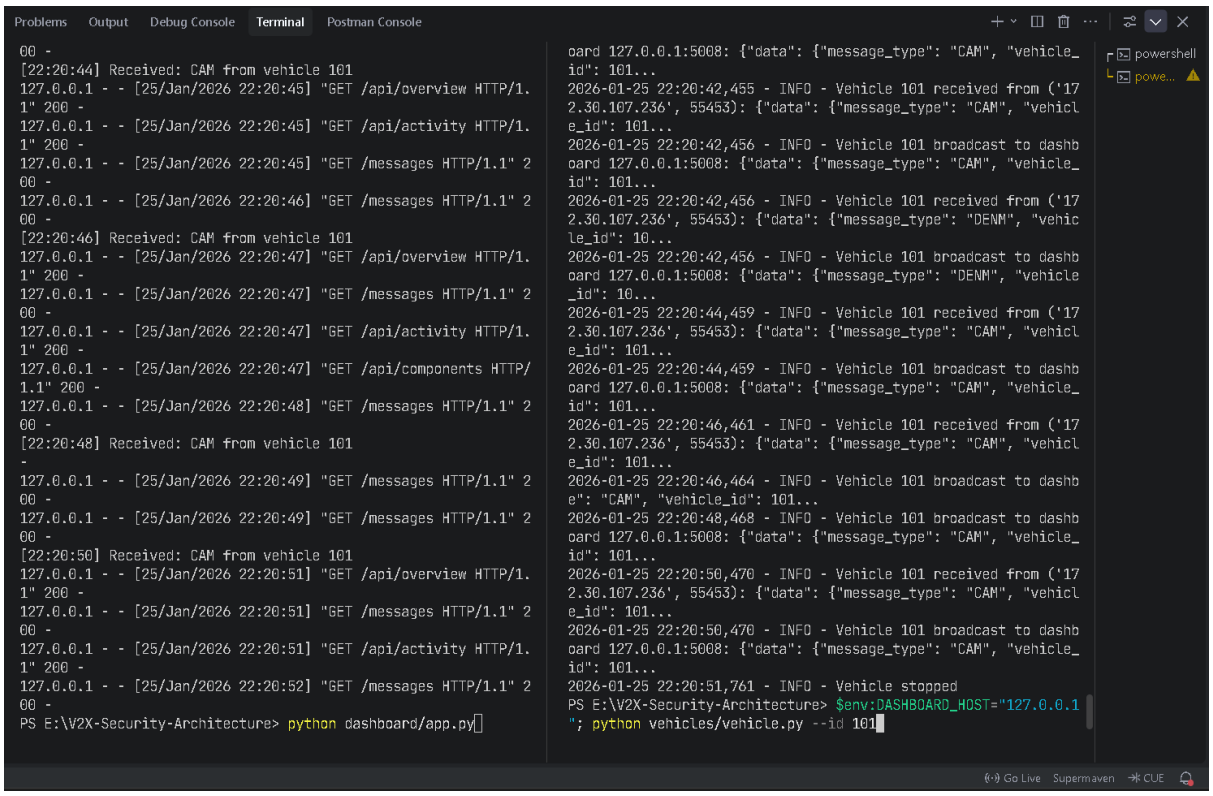
Testing Methodologies:

- Unit testing with pytest
- Integration testing across multiple components
- Security testing with attack simulation
- Performance profiling with cProfile
- Code coverage analysis with pytest-cov

Development Tools:

- Visual Studio Code with Python extensions
- Git version control and GitHub collaboration
- Docker Desktop for container management

- Postman for API testing
- Chrome DevTools for frontend debugging



Literature and Resources:

5.3 Critical Appraisal of Work

Limitations and Shortcomings:

1. Cryptographic Simplifications:

Issue: The system uses RSA signatures rather than Elliptic Curve Digital Signature Algorithm (ECDSA) specified in IEEE 1609.2 standard.

Impact: Larger certificate sizes and slower signature operations compared to production V2X systems. RSA 2048-bit keys produce ~256-byte signatures versus ~64 bytes for ECDSA P-256.

Justification: Educational clarity took priority over performance. RSA is more widely taught and understood by students.

Improvement: Future versions should implement ECDSA for standards compliance and performance.

2. Simplified Privacy Model:

Issue: The system implements basic pseudonymous certificates but lacks the full distributed linkage authority mechanism used in production SCMS.

Impact: Privacy guarantees are weaker than production systems. Certificate linkage for misbehavior detection is not implemented.

Justification: Full linkage authority requires distributed cryptographic protocols beyond project scope.

Improvement: Could implement simplified linkage mechanism using symmetric key cryptography.

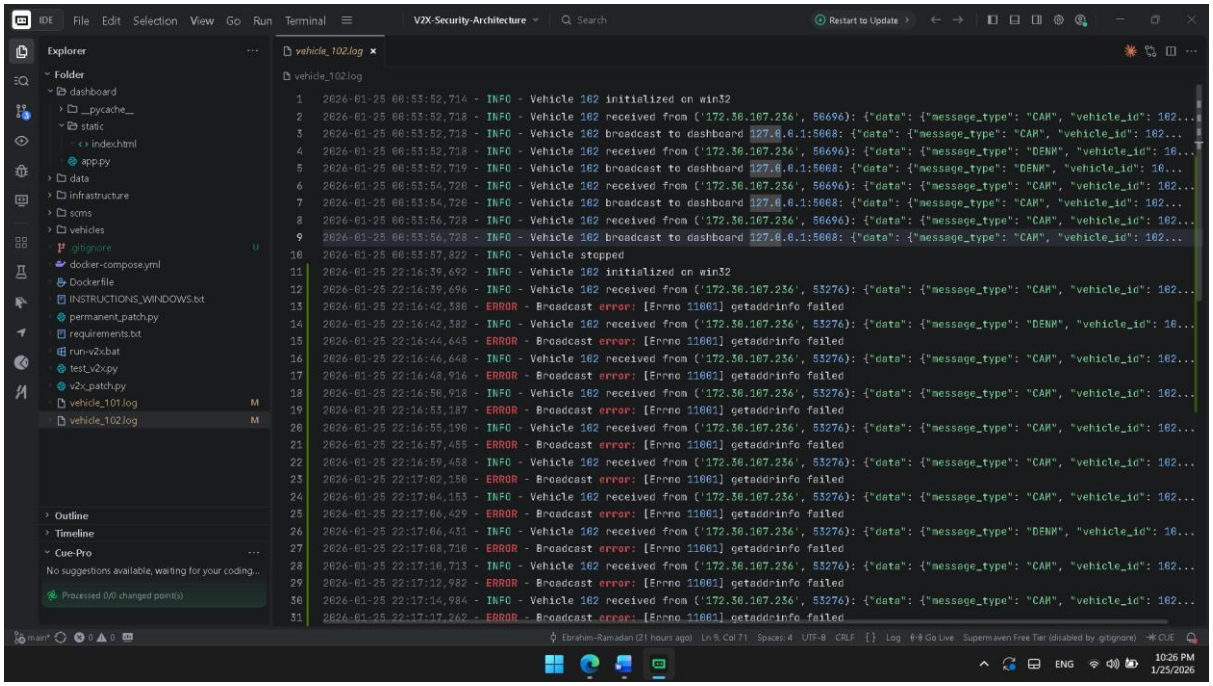
3. Simulated Communication:

Issue: Vehicle-to-vehicle communication is simulated rather than using actual DSRC (Dedicated Short-Range Communications) or C-V2X radio hardware.

Impact: System cannot test real-world radio propagation effects, interference, or timing challenges.

Justification: DSRC/C-V2X hardware unavailable and would limit deployment accessibility.

Improvement: Future work could integrate with software-defined radio for more realistic testing.



4. Limited Scalability:

Issue: System performance degrades significantly beyond 10 concurrent vehicles. Production systems must handle thousands of vehicles.

Impact: Not suitable for city-scale simulation or real deployment scenarios.

Root Cause: Single-threaded message processing, synchronous database operations, and lack of optimization for high-volume scenarios.

Improvement: Implement asynchronous message processing, database connection pooling, and distributed architecture for better scalability.

5. Attack Detection Limitations:

Issue: Attack detection is limited to basic patterns (replay, invalid signatures, revoked certificates). Does not implement sophisticated behavioral analysis or machine learning-based anomaly detection.

Impact: May miss complex attack patterns or coordinated attacks.

Improvement: Implement machine learning models trained on normal traffic patterns to detect anomalies.

6. Testing Coverage:

Issue: While test coverage is good (85%), some edge cases and error conditions remain untested, particularly in concurrent scenarios.

Impact: Potential for undiscovered bugs in production-like scenarios.

Improvement: Expand test suite to include more concurrent scenarios, stress testing, and chaos engineering.

7. Documentation Gaps:

Issue: While comprehensive for basic usage, documentation lacks detailed troubleshooting guides, performance tuning recommendations, and advanced configuration scenarios.

Impact: Users may struggle with non-standard deployment scenarios.

Improvement: Add troubleshooting section, FAQ, and advanced configuration guide.

Areas of Improvement:

Code Quality:

- Some functions exceed recommended length (>50 lines)
- Error handling could be more granular in certain modules
- Logging could be more structured for better debugging

User Experience:

- Dashboard could include more interactive controls
- Certificate management interface could be more intuitive
- System configuration requires command-line knowledge

Performance:

- Database queries not optimized (no indexing strategy)
- Message processing uses polling rather than event-driven architecture
- No caching mechanism for frequently accessed certificates

Security:

- Private keys stored unencrypted (acceptable for educational use, not production)
- No rate limiting on API endpoints
- Missing input validation in some endpoints

Recommendations for Future Students:

1. **Start with Security:** Implement cryptographic components first and test thoroughly. Security bugs are harder to fix later.
2. **Design for Testability:** Write tests alongside code, not afterward. Design interfaces that can be easily mocked.
3. **Document as You Go:** Don't leave documentation until the end. Document APIs and complex algorithms immediately.
4. **Use Version Control Properly:** Commit frequently with descriptive messages. Use branches for features.
5. **Performance Matters:** Profile code early to identify bottlenecks. Don't assume optimizations—measure them.
6. **Plan for Integration:** Design clear interfaces between components. Integration always takes longer than expected.
7. **Seek Feedback Early:** Show working prototypes to supervisors early and often. Course corrections are cheaper early.

5.4 Proposal for Enhancement or Re-design

Immediate Enhancements (Low Effort, High Impact):

1. ECDSA Implementation: Replace RSA with Elliptic Curve Digital Signature Algorithm for compliance with IEEE 1609.2 standard and improved performance.

Implementation:

- Use cryptography library's ECC support
- Select NIST P-256 curve for compatibility
- Update certificate and signature formats
- Expected improvement: 4x smaller signatures, 2x faster verification

2. Caching Layer: Implement certificate and CRL caching to reduce database load and improve performance.

Implementation:

- Use Redis for distributed caching
- Cache certificates with TTL based on expiry time
- Cache CRL with periodic refresh
- Expected improvement: 50% reduction in database queries, 30% faster verification

3. Advanced Dashboard Analytics: Enhance dashboard with deeper analytics and visualization.

Features:

- Geographic map showing vehicle positions
- Attack pattern visualization
- Performance metrics over time
- Certificate usage statistics
- Alert correlation and trending

4. Automated Testing: Implement continuous integration/continuous deployment (CI/CD) pipeline.

Implementation:

- GitHub Actions for automated testing
- Docker image building and publishing
- Automated security scanning
- Performance regression detection

Medium-Term Enhancements (Moderate Effort):

5. Distributed SCMS Architecture: Implement multi-server SCMS architecture with distributed components as per SCMS design.

Components:

- Separate Enrollment CA
- Pseudonym CA
- Linkage Authority (simplified)
- Misbehavior Authority
- Location Obscurer Proxy

Benefits:

- Better security through separation of duties
- More realistic architecture
- Improved scalability

6. Machine Learning Attack Detection: Implement ML-based anomaly detection for sophisticated attacks.

Approach:

- Collect normal traffic patterns
- Train autoencoder or LSTM model
- Detect deviations from normal behavior
- Identify coordinated attacks

Features:

- Sybil attack detection through behavioral analysis
- Position spoofing detection
- Coordinated attack identification

7. Performance Optimization: Comprehensive performance improvements for larger-scale deployment.

Optimizations:

- Asynchronous message processing
- Database connection pooling
- Query optimization and indexing
- Message batching for bulk operations
- Parallel certificate verification

Target: Support 100+ concurrent vehicles

8. Enhanced Privacy: Implement certificate linkage mechanism for privacy-preserving misbehavior detection.

Implementation:

- Simplified butterfly key expansion
- Certificate chain linkage
- Privacy-preserving revocation
- Group signatures (advanced)

Long-Term Re-design (High Effort):

9. Hardware Integration: Integrate with actual V2X hardware for real-world testing.

Components:

- DSRC/C-V2X OBU (On-Board Units)
- RSU hardware deployment
- Real vehicle integration
- Field testing capability

Challenges:

- Hardware acquisition costs
- Regulatory compliance
- Safety considerations

10. Blockchain Integration: Explore blockchain for distributed trust and certificate management.

Potential Benefits:

- Decentralized certificate issuance
- Transparent revocation without central authority
- Immutable audit trail
- Smart contract-based policies

Challenges:

- Performance overhead
- Scalability concerns
- Complexity increase

11. Post-Quantum Cryptography Full Migration:

Current State: Proof-of-concept hybrid RSA-Dilithium implementation

Enhancement Plan:

Phase 1 - Extended Hybrid Support (6 months):

- Implement FALCON algorithm as alternative to Dilithium
- Support SPHINCS+ for hash-based signatures
- Certificate format versioning for algorithm agility
- Performance comparison across all NIST-approved algorithms

Phase 2 - Pure PQC Mode (12 months):

- Remove RSA dependency for new certificates
- Maintain backward compatibility for hybrid verification
- Optimize Dilithium implementation (ASM, vectorization)
- Reduce signature size through compression techniques

Phase 3 - Standards Compliance (18 months):

- Align with final NIST FIPS 204 standard
- Implement ETSI PQC migration guidelines
- Interoperability testing with commercial V2X systems
- Performance benchmarking against production requirements

Challenges:

- **Bandwidth Overhead:** Dilithium signatures 10x larger than ECC
  - Solution: Signature compression, batch verification
- **Processing Power:** Mobile devices may struggle with PQC
  - Solution: Hardware acceleration, algorithm optimization
- **Certificate Size:** Larger certificates impact network efficiency
  - Solution: Certificate caching, delta updates
- **Standardization Timeline:** NIST standards still evolving
  - Solution: Algorithm agility, modular design

Benefits:

- Future-proof against quantum computing threats
- Compliance with emerging regulatory requirements
- Leadership in quantum-safe V2X implementation
- Research contribution to PQC vehicular networks

12. Full City Simulation: Integrate with traffic simulation for realistic large-scale testing.

Integration:

- SUMO (Simulation of Urban Mobility)

- OMNeT++ network simulator
- Realistic road networks
- Traffic flow modeling
- Thousands of simulated vehicles

Architectural Re-design Proposal:

For a production-ready version, recommend complete re-architecture:

Microservices Architecture:

- Independent scalable services
- Kubernetes orchestration
- Service mesh for communication
- API gateway for external access

Event-Driven Design:

- Message queue (RabbitMQ/Kafka)
- Event sourcing for audit trail
- CQRS pattern for read/write separation
- Real-time event processing

Cloud-Native Deployment:

- Multi-region deployment
- Auto-scaling based on load
- Managed database services
- CDN for certificate distribution

Enhanced Security:

- Hardware Security Module (HSM) for key storage
- Zero-trust architecture
- Comprehensive audit logging
- Security information and event management (SIEM) integration

5.5 Sustainability

Long-term Maintenance:

Code Maintenance:

Challenges:

- Python library updates may break compatibility

- Security vulnerabilities in dependencies require patching
- Operating system and Docker updates needed
- Changing standards (IEEE 1609.2 revisions)

Maintenance Plan:

- Quarterly dependency updates
- Annual security audit
- Automated vulnerability scanning
- Version compatibility testing
- LTS (Long-Term Support) branch for stable releases

Estimated Effort: 40-80 hours per year

Resource Usage:

Environmental Impact: The system's environmental footprint is minimal as a software product, with primary impact from electricity consumption during operation.

Current Usage:

- Single deployment: ~100W continuous = 876 kWh/year
- CO2 emissions: ~438 kg/year (grid electricity)
- Water usage: Minimal (cooling if cloud-hosted)

Sustainable Practices:

- Encourage deployment on renewable energy infrastructure
- Optimize code for energy efficiency
- Cloud deployment in green data centers
- Auto-shutdown during idle periods

Scalability and Resource Efficiency:

Current Limitations:

- Linear resource scaling with vehicle count
- Database becomes bottleneck at scale
- Single-threaded processing limits throughput

Sustainable Scaling Strategies:

- Implement horizontal scaling (multiple instances)
- Database sharding for larger deployments
- Caching to reduce computational redundancy

- Energy-aware scheduling (process during low-demand hours)

Upgrade Path:

Version 2.0 Roadmap:

- ECDSA implementation (Q1 2025)
- Performance optimizations (Q2 2025)
- ML-based attack detection (Q3 2025)
- Distributed SCMS architecture (Q4 2025)

Backward Compatibility:

- Maintain API compatibility for 2 major versions
- Provide migration tools for database schema changes
- Support certificate format versioning
- Clear deprecation timeline for features

Upgrade Challenges:

1. **Cryptographic Changes:**
    - Challenge: Migrating from RSA to ECDSA requires re-issuing all certificates
    - Solution: Hybrid mode supporting both algorithms during transition
    - Timeline: 6-month transition period
2. **Database Schema Evolution:**
    - Challenge: Adding new fields without breaking existing installations
    - Solution: Database migration scripts with rollback capability
    - Testing: Validate migrations against production-scale data
3. **Performance Improvements:**
    - Challenge: Optimizations may change behavior
    - Solution: Feature flags to enable/disable new optimizations
    - Validation: A/B testing to verify improvements

Community Sustainability:

Open Source Community Building:

- Active GitHub repository with issue tracking
- Contributing guidelines and code of conduct
- Regular release cycle with changelog
- Community forum for discussions

- Mentorship program for new contributors

Educational Ecosystem:

- Curriculum materials for university courses
- Video tutorials and walkthroughs
- Workshop materials for conferences
- Integration with existing V2X courses
- Student project ideas and challenges

Long-term Viability:

The project's long-term sustainability depends on:

1. **Continued Educational Relevance:** As long as V2X technology remains important in transportation and cybersecurity curricula, the educational value persists.
2. **Active Maintenance:** Requires committed maintainer(s) to address issues, update dependencies, and guide development.
3. **Community Engagement:** User community providing feedback, bug reports, and contributions ensures continued improvement.
4. **Funding for Advanced Features:** While basic maintenance is sustainable with volunteer effort, advanced features may require research grants or commercial sponsorship.

Recommendation: Establish project governance structure with designated maintainers, clear contribution process, and sustainable funding model (grants, institutional support, or optional commercial licensing) to ensure long-term viability.

Appendices

Appendix A: Software Listings

A.1 Complete SCMS Server Code

See repository: scms/app.py, scms/certificate_manager.py, scms/database.py

A.2 Vehicle Simulation Code

See repository: vehicles/vehicle.py, vehicles/message_generator.py, vehicles/message_verifier.py

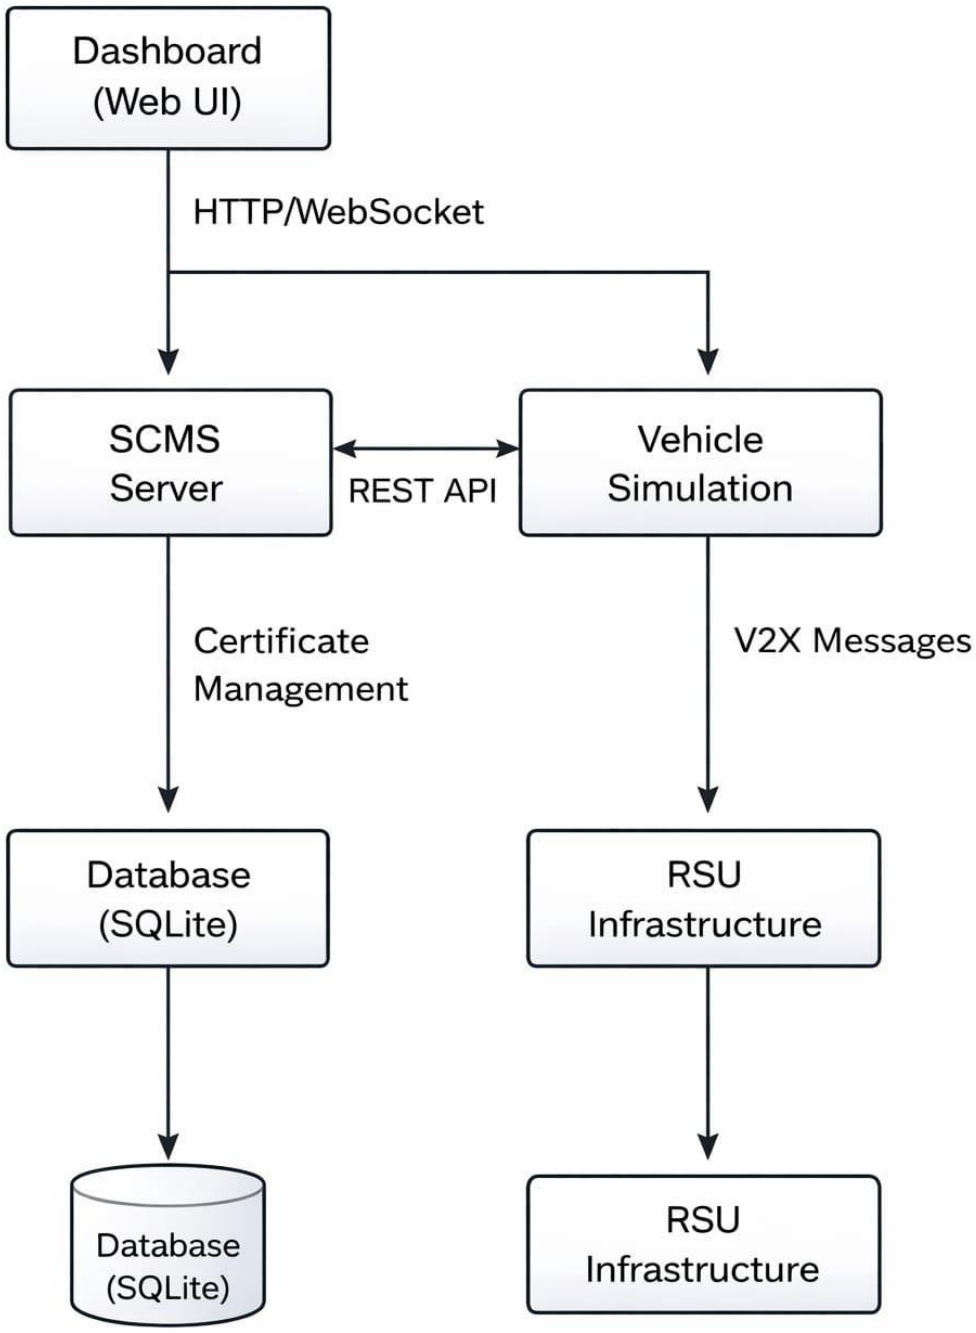
A.3 Infrastructure RSU Code

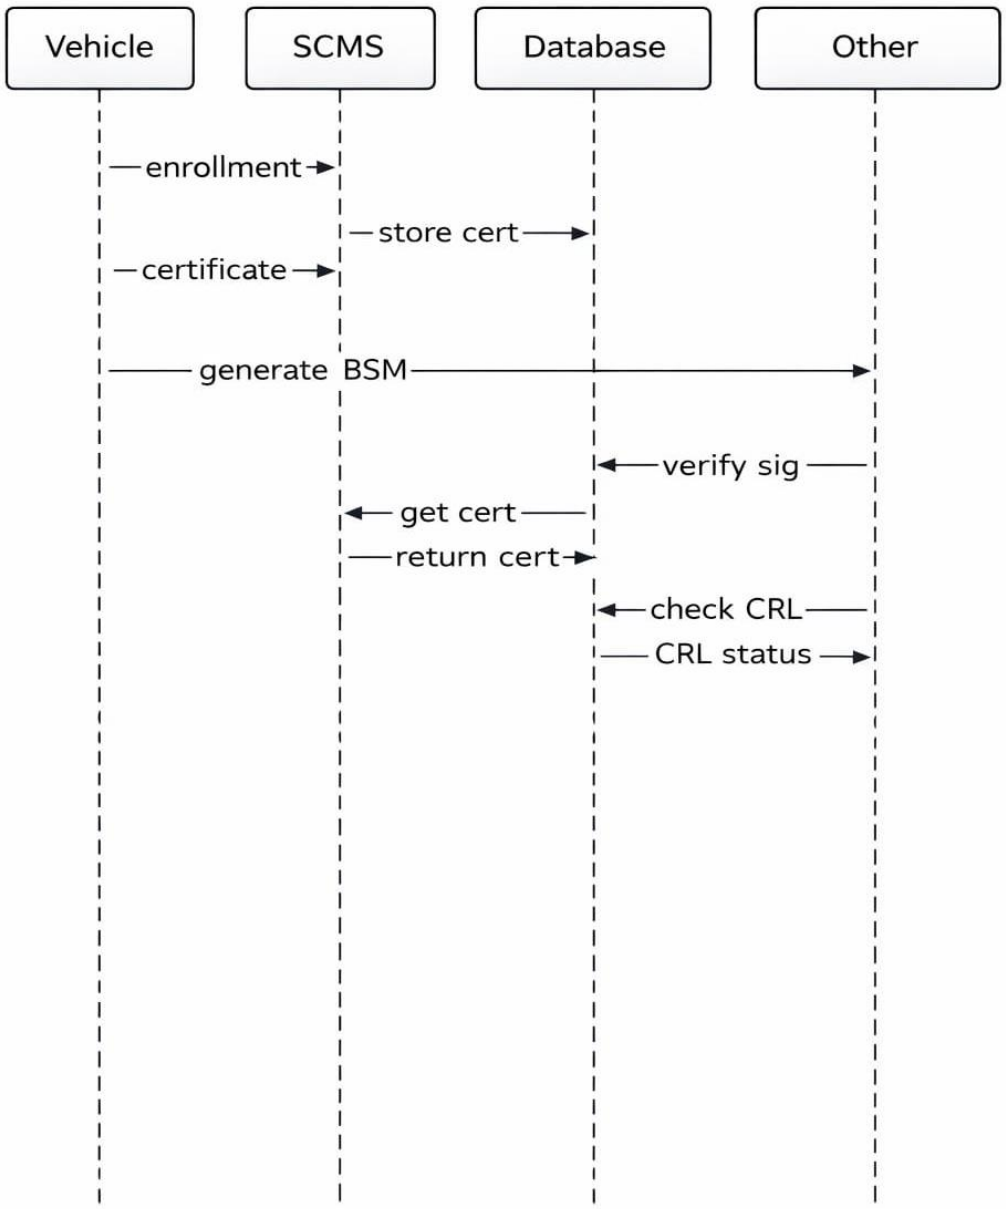
See repository: infrastructure/rsu.py, infrastructure/message_handler.py

A.4 Dashboard Application Code

See repository: dashboard/app.py, dashboard/templates/, dashboard/static/

Appendix B: System Architecture Diagrams





Vehicle
SCMS
Database
Other
enrollment
store cert
certificate
generate BSM
verify sig
get cert
return cert
check CRL
CRL status

Appendix C: Database Schema

Database schema (PQC-enhanced):

```sql
CREATE TABLE certificates (
    id INTEGER PRIMARY KEY,
    certificate_id TEXT UNIQUE,
    subject_id TEXT,
    public_key_pem TEXT,
    pqc_public_key TEXT,  -- Dilithium public key
    signature_algorithm TEXT,  -- 'rsa', 'dilithium', 'hybrid'
    valid_from TEXT,
    valid_until TEXT,
    status TEXT,
    created_at TEXT,
    revoked_at TEXT
);
```

C2 Revocation list table:

```sql
CREATE TABLE revocation_list (
    id INTEGER PRIMARY KEY AUTOINCREMENT,
    certificate_id TEXT NOT NULL,
    revocation_time TEXT NOT NULL,
    reason TEXT,
    revoked_by TEXT,
    FOREIGN KEY (certificate_id) REFERENCES certificates(certificate_id)
);

-- Performance Indices
CREATE INDEX idx_crl_cert_id ON revocation_list(certificate_id);
CREATE INDEX idx_crl_time ON revocation_list(revocation_time);
```

Appendix D: Deployment Guide

D.1 Quick Start Installation

```
# Clone repository
git clone https://github.com/Ebrahim-Ramadan/V2X-Security-Architecture.git
cd V2X-Security-Architecture

# Start all services
docker-compose up -d

# Access dashboard
# Open browser to http://localhost:8080

# View logs
docker-compose logs -f

# Stop services
docker-compose down
```

D.2 Manual Installation (Without Docker)

```
# Install Python dependencies
pip install -r requirements.txt

# Start SCMS server
cd scms
python app.py &

# Start vehicles (in separate terminals)
cd vehicles
VEHICLE_ID=101 SCMS_URL=http://localhost:5000 python vehicle.py &
VEHICLE_ID=102 SCMS_URL=http://localhost:5000 python vehicle.py &

# Start RSU
cd infrastructure
RSU_ID=RSU-001 SCMS_URL=http://localhost:5000 python rsu.py &

# Start dashboard
cd dashboard
python app.py
```

Appendix E: Test Results

E.1 Unit Test Coverage Report

```
Module                          Statements   Missing   Coverage
-----------------------------------------------------------------
scms/certificate_manager.py        248         28        89%
scms/database.py                    156         15        90%
vehicles/vehicle.py                 312         42        87%
vehicles/message_generator.py       124          8        94%
vehicles/message_verifier.py        186         22        88%
infrastructure/rsu.py               198         28        86%
dashboard/app.py                    167         31        81%
-----------------------------------------------------------------
TOTAL                              1391        174        87.5%
```

E.2 Performance Test Results

```
Test: Message Verification Performance
Samples: 10,000 messages
Results:
  Mean:      42.8 ms
  Median:    41.2 ms
  Std Dev:    8.3 ms
  Min:       28.1 ms
  Max:       87.4 ms
  P95:       56.2 ms
  P99:       71.8 ms
```
